it entirely in assembly you will achieve *very* little benefit.

Correction, 3 to 4 times a week.

>For _what_ exactly?<

You name it.
I lose keyboard control quite a bit, only way to get it back is to reboot.
I get the system is busy blue screen all the time, for many programs
System and program settings change for no reason.

Those are a few of the more common ones on my machine, I administer four other machines in the office, peer networked. All of which have Pentiums and 16 Mb of RAM or better and there all still sluggish.

One of them stopped asking for a user name and password when you first boot up, then you have to shut down and log on as a different user to get on to the network. Compaq has been no help MS support is stumped. Windows magazines Fred Langa was sumped. It seems I spend more time troubleshooting Windoze than actually getting any work done.

What's really funny is Win95 is better than it's predecessors. I used and swore by Wintel machines for ten years, then I used my first Mac at a computer store, after 20 minutes I finally realized what a computer can be. I'll never go back.
==

Chris,

since you used HTML on your MS News to write about how bad Microsoft products are, I am replying to this with HTML too. Some (most) will not be able to see this properly, but I know that you will, unless of course you decide to read it at home on your superior Mac. :-)

What you describe is going on with your Windows 95 set-up is totally abnormal, and you know it. But, this is an advocacy group, and not the proper place to solve your technical problems.

However, since you know that the majority of us who use Win95/NT on a daily basis and set-up similar systems in businesses every day for a living do not have these same problems that you describe, on a routine basis, something is obviously wrong with your set-up and the compettence of the computer support staff in your shop.

To blame Microsoft and Windows for this is shortsighted and stupid.

P.S. Hey at least Ross Perot got his money out in cash from an investment that was going nowhere (NeXT). You notice that he didn't take any Apple stock. It's interesting how a company that's losing money by the ton itself, buys for $400 million another dud, to help Ross out. Don't you think that someone should investigate this?

Release one on the Mac and you'll get the same reaction.

> Many graphics cards I known of on the PC will work without a
> driver either. The reason is called the VESA video BIOS.

Yes, at VGA. No larger screens, no panning etc. Many of these features are in QuickDraw so you don't need any other driver to support them.

Well put, but that is that is also part of the API for application services? For instance, what if the menu system was the video driver? Odd example I know...

How do you do that if they keyboard's dead? Hit reset on the CPU, or just power down?

>I get the system is busy blue screen all the time, for many programs

Have you checked your hardware?

>System and program settings change for no reason.

Such as?

>One of them stopped asking for a user name and password when you first boot
>up, then you have to shut down and log on as a different user to get on to

That didn't just 'happen' - a user did that. I suggest going to the Network control panel and checking what it says.

>the network. Compaq has been no help MS support is stumped. Windows
>magazines Fred Langa was sumped. It seems I spend more time troubleshooting
>Windoze than actually getting any work done.

Err...that's a pretty simple one to solve, no?

```

Defrag: best available is Diamond Edge (it also has the facilities to back up your SCSI partition tables and scan the drives for errors, with automatic correction). Contact Oregon Research for the latest version.

UVK (Richard Karsmaker, I believe) is the best virus detection/removal system for the ST. A freeware virus killer is called "Virus Killer" (creative, eh?) and will detect and remove most floppy boot sector viruses.

I don't have immediate contact information for either of these folx, but OR is available through Long Distance information - they're in Tigard, Oregon, area code 503.

Chris is welcome to UUE them to me and i'll post them on an
ftp site. Sorry, but uploading is not possible here.
>
> Slideshows are not desirable for a real test. You can't tell what part of

Twenty images in 26 seconds? Where the waiting? :)
This will be true for a single image as well.
(We could use the 6 remaining seconds as a "point spread" :)

>
> What I think I may do is tile together a very large image (say, 3000x3000

Ram disk if fine fine here. Is 20mb/sec to fast? Hell, can I just blit
the
image to another area and display it? Would that be cheating?

>
> (Funny thing is, I just realized my challenge won't prove anything one way
> or the other... both sides will have things to fall back on, because it

Actually (depending which server post my mail first) I just wanted to
see
how much "blow away" really ment. My other post will include the ftp
address
for a file we all can use for a simple test. It looks like from Chris's
post above that we would have problems timing a test if each event takes
less than a second.

Perhaps I read too much into your comment, then.

Nonetheless, there are still plenty of *corporations* that have dedicated
programmers. I dislike some of Adobe's business practices as much as
anyone, but they have long used highly skilled programmers to write tight
assembly code for Photoshop filters.

>>Assembly is hardly a "corporate no-no". There are tons of commercial
>>programs which use it.
>
>Corporations are more concerned about getting their product onto the street
>on time and on budget, no time for optimizing.

See above. There are a large number of programs for which performance is
an important enough problem that optimizing does take place.

>The fact that simple apps come on multiple disks or CD's is a testament to
>this when compared to relatively similar apps written in tighter code.

Actually, with the proliferation of CDs, it's often cheaper to burn a
single CD than it is to dupe a single floppy. And as long as you've got
that much space, you might as well use it for something... like online
documentation, which is much more common on the Mac and PC.

To give you an example of a really well done Macintosh application,
consider Word Perfect 3.5 for Mac. It is a very nice, easy to use, full
featured word processor. It is hellaciously fast. And the core word
processor itself takes up just 5.6 MB on my disk (the app itself, and the
files necessary for spell and grammar checking). The remainder of the
files (file format conversion filters and various forms of online
documentation) occupy another 7 MB.

>>Writing programs entirely in assembly is out, though. There's no purpose
>
>It is "out" in the Mac and Win world because it takes too long, it is easier

It takes too long no matter what platform you're on.

> In the Atari world, it is "in" because a highly
>optimised app (or OS in the case of MagiC) can be run with decent speed on 9
>year old equipment.

Exactly. And even so, with the use of the 90/10 model I detailed, you could get programs that ran just as fast, but were far easier to write and maintain.

For example, GEM user interface code is very easy to deal with in C. Not so in assembly. And you'll never notice the speed difference, because the code is not CPU intensive, with the exception of GEM drawing routines. The drawing routines of any OS are a great candidate for assembly.

Uhhh, how about all of the 9500 and 8500 type chassis based machines directly from Apple? Or any of the PowerComputing machines which ship with various ATi cars? Or the Motorola machines which have an ATi card on the motherboard? You mean those ones?

Maury

1) Perhaps the distinction is only in the packaging and marketing of the
cards.

2) The Number Nine Imagine 128 works in both Macs and PCs.

I can't think of any other PCI cards that are exactly the same for Macs
and PCs off hand... I'm sure other people could think of some more examples.

> >With PCI Macs, there is no special hardware needed to support Macs as

What precisely do you mean by "PC video board"?

ATI's Xclaim VR seems to be very similar (if not identical to) the 3D
Xpression+TV. I don't know whether the cards are precisely the same with
different packaging, labeling, and drivers or whether they have differences
between them that would preclude one being used on the other platform.

As I understand it, some graphics cards that work on Macs automatically
```

accelerate graphics, and need an extension (or control panel) to disable acceleration (the extension/control panel can also be used to patch portions of the card's driver).

This is dependent on the card maker's implimentation though (if the drivers are not on the card, then they'll have to be loaded from software).

Actually (and this depends on implimentation), some cards automatically accelerate QuickDraw operations and don't strictly need an extension.

I wonder though, can PCs change color depth or resolution without a driver or is there just one specific resolution/color depth that is available if you don't have the appropriate driver loaded?

It's possible that there are exceptions, but with all the graphics cards that work in Macs that I know of, you can change resolutions/color depths (on the fly) even if you've installed no software on the Mac for that card (so you may have no acceleration, but it will work normally otherwise).

> >To enable graphics acceleration, an extension would have to be loaded.

Except in those cases where the extensions job is not specifically to enable the card so that it works.

Still, some companies have their own home-brewed drivers for their cards
quite often anyway (not a big deal at all, but...).

>   There is also

Possibly. I don't know the details of it though.

What desktop are yo using? If MagiC/Ease you can do this from the
desktop by selecting the drive icons you want searched, go under the
File menu and select the 'Find' option, type in the file mask you want
and let it go to it! You will be shown windows for all occurrences of
the mask.

If OTOH you're using the standard old TOS desktop, get the shareware
file selector 'Selectric' and use its very nice FIND function to search
for the file mask you specify.

Tell me about the atari.... so far... all I know about the atari is that it is
good for the
use of music(cheap price too). What are the other advantages of the atari. I am
majoring in Computer Animation. I am looking at different types of Computers,
OS,
Etc. Does atari offer capabilities that exceed the Pc's, mac's, and AMiGA's,
(wheather in graphics, sound, etc.)???

tell me about the atari's...........................

The current revision of the S3 generic driver (Win95) does support
resolution changes whithout rebooting.

I said nothing of the kind. It's genuinely pathetic when you MacVocates must resort to lying to make a point. Note that the fellow said that the card in question required special software be added to the system. This is precisely what I have been saying would be required for a platform independent video card on a Mac. You can't even honestly characterize information that's in front of you much less anything more distant.

Any vid card not catering to the Mac will have the same configuration complexities as a PC card.

There are a couple. I usually use the "find" function built into Little Green Selector (it's always readily available), but a WHEREIS program exists (probably several of them, actually).

How can you tell that this MacVocate is lying?

His mouth is open.

I have explicitly stated before, for those to dense to get the reference, that VGA++ was an acknowledgement that the Mac's video cloning standard was more robust. This person's Diamond problems don't contradict anything I have said. Furthermore, Diamond is an exceedingly poor example.

I'd just love to see the mess they could make of Mac PnP...

So a native OS like Be runs faster than an OS running under double
emulation, big deal!

>3-4 times a *day*? <

Correction, 3 to 4 times a week.

>For _what_ exactly?<

You name it.
I lose keyboard control quite a bit, only way to get it back is to reboot.
I get the system is busy blue screen all the time, for many programs
System and program settings change for no reason.

Those are a few of the more common ones on my machine, I administer four other machines in the office, peer networked. All of which have Pentiums and 16 Mb of RAM or better and there all still sluggish.

One of them stopped asking for a user name and password when you first boot up, then you have to shut down and log on as a different user to get on to the network. Compaq has been no help MS support is stumped. Windows magazines Fred Langa was sumped. It seems I spend more time troubleshooting Windoze than actually getting any work done.

What's really funny is Win95 is better than it's predecessors. I used and swore by Wintel machines for ten years, then I used my first Mac at a computer store, after 20 minutes I finally realized what a computer can be. I'll never go back.

It is a non-accelerated generic driver that uses VESA PMI to set and
change video modes. Thanks for pointing out the name.

>>and maybe NT also have generic drivers that use the VESA interface. (I

>Not. At least nothing like OS/2's GENGRADD.

Probably not, though there is no reason, other than poor performance, that
NT should be missing drivers for VESA based frame buffer access.

Yes. NT has the equivlent of these as well. (And the Linux XFree86 servers
each support a family of video adapters as well.)

>>could be wrong.) Linux definately does. (Unaccelerated X-Server)

The size of the driver and where it is located is irrelevent. As long as
it doesn't reside as part of the kernel, and takes hardware specific
features and abstracts them to a standardized API, then I consider it a
driver.

A driver on a ROM is still technically a driver, no?

>There are Mac drivers, but their nature is different from what we expect

[deleted]

>driver, which has to be on the ROM in the card itself. But then, part
>of MacOS is in ROM, so this is not surprising.

After doing a little checking, yes indeed, I agree with you. Many Mac
video cards do indeed place their driver on a ROM chip onboard the card
itself.

Regardless, a driver in ROM is still a driver, albeit one that
doesn't require installation. :) A good thing, for ease of use.

In any case, I consider having things in ROM as a fairly big disadvantage
when it comes to updates and bug fixes. Of course a common thing on the
PC. sigh. :(

Still, I'd much rather stick in a disk and install new software instead of pulling a ROM chip or loading a patch. (Even with Flash RAM I'd still have to pull the card, reset the safety jumper, and then do the Flash RAM update.)

Revised claim:

"The Mac typically supports accelerated video through the use of drivers embedded on the video card in a ROM chip. This eliminates the need to seperately install drivers. Certain developers may choose to ignore this convention and implement the driver PC style."

"The PC supports non-accelerated video through the VESA video bios, which on many video cards functions much like the Mac style ROM chip, except mostly without acceleration features. Some acceleration features may be enabled by VESA 2.0. For accelerated video, the PC relies on drivers loaded by the OS at boot time typically from the hard disk."

So you won't mistake which one is for the Mac, and which one is for the
PC.

>
>   As far as XClaim drivers go: I'd rather just get the PC version
>   and spend 33% less. (Rage II ?)

Actually, the prices of ATI cards are fairly the same for both PC and
Mac versions. The exception is the low end ATI Graphics Expression
which has no Mac equivalent, but isn't faster than built in VRAM
based Mac graphics subsystems found in PCI Macs, and the fact that in
many Mac clones (Motorola and Power Computing in mind), an ATI Mach 64
264VT chipset is standard built into them. If that Mach 64 is paired
with DRAM, this is already the performance equivalent of the Graphics
Expression. If that Mach 64 is paired with VRAM, the equivalent would
be the Pro Turbo. Thus, Mac graphics cards, in essence have to be high
end, high performance, or you will be throwing money with a low end card
that isn't faster than the fast built in graphics system.

Bigotted? How so. My comment was made in reference to the "Corporate"
programming companies, not individual code hackers. Without naming any
specific "Corporations", I think you should be able to figure out to
whom I reference this point to.

Surely there are hobbyists and small guys programming in their basement
that do a wonderful job on software for all platforms. You just don't
see their stuff in the stores or in the catalogues etc. because it is
mostly PD/Shareware.

>>Many Atari programmers work in machine assembly code, a corporate no-no

>
>Assembly is hardly a "corporate no-no". There are tons of commercial
>programs which use it.

Corporations are more concerned about getting their product onto the street
on time and on budget, no time for optimizing.

The fact that simple apps come on multiple disks or CD's is a testament to
this when compared to relatively similar apps written in tighter code.

>Writing programs entirely in assembly is out, though. There's no purpose

It is "out" in the Mac and Win world because it takes too long, it is easier
to use higher level languages. In the Atari world, it is "in" because a highly
optimised app (or OS in the case of MagiC) can be run with decent speed on 9
year old equipment.

All the best,
Chris @ Computer Direct

If you must guess, at least don't post your guesses. VESA has the ability to do all resolutions the card can do, at all colordepths.

Granted, I'm talking about DOS here, but VESA is a graphics card addressing standard, and it doesn't require a software driver (made especially for the graphics card) in order to work.

I don't know why ATI choses to do that.

It could be they are targeting a different customer base. ;)

>   The Mac could be using VME
>   for any reall effect PCI has...

After checking their website, it looks as if the 3D Xpression+PC2TV isn't quite as good as the XClaimVR.

They both accelerate 2D and 3D graphics.
They both have television output.

Only the Xclaim has video input built in (from VCR or camcorder).

With an extra card, both can be used as a TV tuner, but the PC's version of the add-on card is what provides the video input.

>   As far as XClaim drivers go: I'd rather just get the PC version
>   and spend 33% less. (Rage II ?)

To have equivalent features for the two cards (both with 2MB RAM):

For the Mac you would purchase the XClaimVR and the XClaim TV tuner
($229.95+$89.95 = $319.90)

For the PC you have to buy the 3D XPression+PC2TV and the apprpriate TV tuner card from ATI.
($162.95+$119.95 = $282.90)

That's a 13% ($37) price difference.
(Prices are from Cyberian Outpost <http://www.cybout.com/cyberian.html>)

I don't know what the differences between the memory systems are. The XClaim uses SGRAM and the XPression uses "single-cycle DRAM memory". Whether those are the same or not or whether one is faster or not, I do not know, but that could possibly account for the final price difference.

I didn't see a "single-cycle DRAM memory" or any memory upgrade for the

XPression listed at Cyberian Outpost, though that doesn't mean that such
an upgrade doesn't exist. The 2MB upgrade for the Mac is $84.95.

Actually, if a GPF occured, my experience tells me to better shutdown and
reboot the system. This is because there is already some corruption in the
memory. I encountered several times after a GPF, everything looks OK but
program which are stable (eg print manager) will themselves encounter GPF.

>XClaim uses SGRAM and the XPression uses "single-cycle DRAM memory".

SGRAM is the same thing Matrox is claiming that's faster than DRAM and is used in the PC only Mystique cards. Like DRAM, SGRAM is single ported. Matrox is also using something dualported they say is faster than VRAM ---heck, I forgot the alphabet soup--- for the Millenium cards. Check http://www.matrox.com to read more about these sort of memories in particular. And when you're there, enjoy the feud they are having with ATI.

As for as the Xpression goes, that's just plain DRAM. I would say both have the same ATI chipset, but the use of SGRAM on the Xclaim card makes it more expensive the Xpressions card.

It would be *suicide* for a card manufacturer to sell a video card with DRAM because in the Macintosh side, the levels are much higher. You can't sell a card whose performance is lower than the built in video of a PCI Mac---which has dual ported VRAM standard. In the PC it's different because for a lot of them, the video is not built in to the motherboard, and second, if they were, they use DRAM. Price is very

important in the PC side because of heavy competition and OEM bundling.
Performance is more important on the Mac side because of higher
expectations.

Rgds,

Obviously more physical memory not more virtual memory makes your computer faster. VM does not slow a machine much as long as you don't "depend on it too much" as you say and cause the hard disk to be thrashed to pieces. Just the extra VM layer shouldn't slow things down too much - lookups must be done to ensure memory protection anyway - particularly as it can be very helpful.

Most systems do not take kindly to running short of memory. Running a computer slightly slower all the time and not crashing is IMHO better than running it slightly faster and then getting _bad_ crashes (i.e. disk corruption and/or reboot) when Netscape messes up and gobbles up loads of memory. Or when you're compiling Modula-3 programs (why I needed the extra MB :)

YOu can do large screens and panning with VESA 2.0.

However, using VESA2.0 disables the majority of acceleration features on a
card. :(

DOS SVGA games are typically the only real users of VESA2.0, mostly because they don't have the choice of using accelerated drivers..

>Odd example I know...

Unlikely. Using OS/2 as an example, the API layer(PM) usually calls down to a lower level of software, like the graphics engine (the GRE), which then breaks down complex operations into simple easy to accelerate ones. These operations are then sent to the device driver (GRADD), which actually talks to the HW. If the GRADD replies that hardware cannot perform that particulr operation, then the GRE emulates the operation.

This is also why drivers can differ wildly in quality, even within the same card family. Developers may initially implement a driver accelerating very few features, then slowly add acceleration as the driver improves.

Of course, I acknowledge that there are exceptions to everything. :)

I will tell you one thing. The SVGA DOS game I have that uses VESA 2.0
ran faster than its Windows 95 equivalent using DirectX.   On an action
game like Mechwarrior, it shows.

Talk about GRADD. GENGRADD in OS/2 is the only driver I know that must use VESA 2.0 (except I suspect, some Linux X-free drivers). I get all sorts of resolutions without installing drivers for the video cards. Furthermore, I can shut down the machine, change the card, and reboot back into the same resolution. It's slower than the dedicated drivers, but surprisingly, on a Cyrix P166+ and a card with fast frame buffering, you can do full window drags and play Quicktime movies with surprising speed. I have a Matrox Millenium, but I have tested this with a Cirrus Logic, various S3 and an ATI Mach 64 card.

However do not confuse Quickdraw and Macintosh graphics with non accelerated VESA drivers. While I can plug and play graphics cards on OS/2 with GENGRADD, I don't do it with true native acceleration---just the sheer speed of the OS/2 GRADD driver and GRE system. The Mac is different, install and acceleration is instantaneous. Extensions are for patches and control settings.   The driver for the Mac card must be built into some ROM, and when the machine boots, the Mac must detect the card, patches the trap dispatch table to vector calls into the card's ROM (instead of its equivalent in the Toolkit ROM). At least that's my theory anyway.

Rgds,

Chris

On my 100MHz Pentium, opening a folder in the explorer (WinNT4) takes several seconds as the OS needs to open every application to retrieve the icons for that file. If I smaller icon, it's faster as the rendering is faster. On my Falc, it's faster as it don't have to open every application to read the icon.

Your definition of bearable is seems to be different from mine. Not to
mention I've never used the word "annoying" when describing my Mac.

sometimes my keyboard goes dead, most of the time it works partially, I've
tried diff. ones so I can't see how it's the hardware.

> >I get the system is busy blue screen all the time, for many programs
>

My point exactly, on a Mac, if for some strange reason there was a critical
problem it would let me know, not give a bunch of addresses, this might be
interesting or useful to a techie, but not to me.

> >System and program settings change for no reason.

When I booted up this morning my desktop icons were all over the place and
the volume was muted. these aren't system settings(maybe the volume thing
is?) but they're the most recent

actually, the user did nothing, all the network setting a correct. If it
were as simple as a setting change it would be possible to make any
networked win95 machine do this, give it a try. When networking is turned
off, the choice to close all programs and log on as a different user isn't
available.

The design of the PC and Mac versions of the following cards: Matrox Millenium, the ATI Mach 64 cards, even the Diamond Javelin to the Stealth are about the same.

Even the chipsets are the same. The Motorola MacOS motherboards use the same ATI 264VT chipset as the ATI Graphics Expression cards for the PC.

Take a look at the Matrox Millenium for the PC and the Mac. Both are absolutely identical in pictures, with the only difference being the Mac version being longer because it has 4MB on it as base instead of 2MB.

> I said nothing of the kind.

"JEDI", you've been saying exactly that for the last two weeks. To be exact you've continually made several claims:

a) PC based display cards don't need drivers (just plug in a SVGA card and off it goes)
b) Mac cards need drivers
c) PC cards won't work on the Mac
d) ISA works on multiple platforms
e) Mac cards are nothing more than "dumb frame buffers"

etc etc. Whatever turns your crank I suppose.

> It's genuinely pathetic when you
>   MacVocates must resort to lying to make a point.

Yeah, sure.

>   Any vid card not catering to the Mac will have the same configuration
>   complexities as a PC card.

That's because it will need to work on the PC. That's called "lowest common denominator".

Several such programs exist, I believe Parafin is a popular one.

In order to launch programs from it, however, you will need an AV-Server.
I recommend Thing.

However, in the Philadelphia area, the Aptiva's were in very short supply, even well before Christmas. I know b/c I was considering buying one from Radia Shack.

Hello all,

I'm sitting on a load of lzh files that i can't seem to decompress. I have LZH201L.TTP and ARCSHELL but I'M stuck. Sometimes I get cryptic error messages (sorry, I didn't write them down) about the archives not existing. I'm sure of the path and procedure so I'm perplexed.

All i really want is a down and dirty little utility that will decompress these lzh files. Please help me!

Thanks in advance

Mykle

If your talking about the file I posted,
just for giggles, the (my) Falcon will
load it at full picture size (virtual screen)
at 16bit color in 10.2 seconds. Pretty slow
compaired to the T060 :(. But a good three seconds

faster than my Quadra :).

Mike

>Perhaps I read too much into your comment, then.

I think that there is way too much emotional attachment to silly pieces
of silicon and plastic. We could all take a lesson from Mr. Sinclair.

To give you an example. MagiCMac is a complete 32 bit preemptive
multitasking
OS with memory protection, threads, signals, pipes etc. etc. etc. for
the Mac
it is shipped on a single 1.44 MB floppy complete with a really slick
desktop
called Ease which I prefer hands down to the Mac Finder. It is faster
and more
stable actually.

Sure, MagiCmac does not have some of the other features (of which value
is

debateable) of MacOS.

An excellent example of what can be achieved when the time and energy is
put
into it.

>Exactly. And even so, with the use of the 90/10 model I detailed, you
>could get programs that ran just as fast, but were far easier to write and
>maintain.

Not being a programmer, I cannot really debate this with any authority. Others
will have to do that for me. All I know is that Papyrus under MagiCMac on my
Mac outperforms Word perf 3.5 on the same Mac. Faster loading, faster scrolling
 etc., and yes I agree WP 3.5 on the Mac is very fast ... for Mac word pro's.

All the best,
Chris @ Computer Direct

I use the older LHARC.TTP. It works fine with drag and drop
or as an installed application.

Do not forget that 95 did not sell anywhere near the predicted numbers.

Just because people were buying one thing doesn't make it better. Sales
and good products many times have no relation at all.

> The end result was that IBM scrambled like mad, according to a Radio
> Shack executive friend of mine, shipping "Free coupons for Windows 95"
> to go with every Win3.1/DOS pre-loaded Aptiva, still sitting on shelves
> and in warehouses.

Maybe these machines were simply left-overs from the DOS/3.1 mass. If
95 is doing so damn good why do I still see Win 3.11 and DOS in even
mass catalogs such as Global? Why do 99% of the people I know still use
Win3.1 and DOS? I am not saying you are wrong and I am right. Only that
that situation can be interpreted in many different ways. This "Radio
Shack executive" is nomore on the inside than me.

It would not have been worth IBM's time to go back and "debox" and
reload 95 on these machines. There are many reasons for not having 95 on
them to start with this is only one.

According to him. But who knows the REAL truth? Sounds like a case of a
single persons perception to me.

If you want to make sure I read your reply email it. I do not frequent
the news groups.

It all depends on how the game is programmed.

It is very possible that a DirectX game that takes advantage of
acceleration feature can end up faster then a DOS game that doesn't.

>>> Well put, but that is that is also part of the API for application

>Talk about GRADD.

Just a note of clarification for those that don't know.
GRADD is not GENGRADD.

GRADD stands for GRaphics Adapter Device Driver. This is a new driver
architecture introducted first with OS/2 PPC and then OS/2 Merlin.

GENGRADD is a driver written to the GRADD speficication that supports
video cards generically via VESA video BIOS routines and linear frame
buffer.

>However do not confuse Quickdraw and Macintosh graphics with non

>ROM (instead of its equivalent in the Toolkit ROM). At least that's my

>theory anyway.

You are probably right. This is the way the OS/2 GRE works with GRADD video drivers as well. The GRE dispatch table is altered by the driver when it loads. Any entries not altered, are set to point to software graphics functions.

Until Merlin, the OS/2 GRE did not have a software implementation for many GRE functions. This made OS/2 video drivers large and difficult to write, as all the functions had to be supplied by the driver vendor.

Unfortunately, being able to run unimplemented functions in software is something I recall Windows has had for a long time (I could be wrong).

It should not be difficult to have something like GENGRADD for Windows, however, no vendor would ever consider actually releasing a card that used such a driver.

There are now extensions to the VESA speficication (VESA VBE/AF) that allow use of accelerated features, but these extensions are rarely supported at the present time. (See the Display Doctor 5.3 Universal VBE extensions for details. http://www.scitechsoft.com/sdd.html)

If you would like Michael, I can time this file for you
on the DirecT60 in various packages, such as ImageCopy.
Photoline and DA's Repro and post times for rotations,
Filters etc.

Where di you post the file?

All the best,
Chris @ Computer Direct

Oh, i'm already sold:) But it would be fun!
>
> Where di you post the file?
>
> All the best,
> Chris @ Computer Direct

I guess my other post didn't make it
out from my other news server:(. Tim
wanted a jpg file we all could use for
a common test. There is a lot more
involved in displaying the .jpg than
pure processor, but I thought it would
be fun. Especially as he is using standard
Mac video and the T060 you have is probably
using the ATI card :).
Anyway it is a file called ab.jpg.
It's about 230K and around 933*1300 res 24bit.

ftp.ridgecrest.ca.us/pub/users/m/mgrove/

I ran it on my Falcon with a 50mhz DSP/32mhz CPU
and 16mhz bus. The .jpg and viewer (jpegv222.prg)
were located in a ram disk set up in ST ram.
Operations were performed in fast ram. The image
was displayed in a virtual screen (full image size)
in Falcon 16 bit mode. TOS was located in fast ram
(along with a few other apps:).
I timed it with a stop
watch from mouse click to the bell tone that
occurs when the file is completely loaded.
The second fastest way to load it was while
in Apex Media. It loads quicker than the
Apex .jpg viewer, but because Apex resizes the
image it took an additional three seconds.
Oh, the image is the cover of ST Computer,

a Falcon with two Shuttle type boosters attached
to each side of the machine. When Titan gets
the Nemesis over here, I think the load time
will go down quite abit. The 16mhz bus is a
bottle neck now to and from the DSP running
at 50mhz. It will also be nice to run my
Mighty Sonic at 48/24mhz (God providing:).

Mike

Just another point of view. I worked at Radio Shack at the time and we had
to beg other stores in our district to send us Aptivas. We couldn't keep
them in stock... at least after I made sure that they booted up to Windows
and not OS/2.

: The Mac OS has evolved over nine years from System 1.0 to 7.6 with lots of the
: latest and greatest..

It's odd, then, that it still doesn't sport pre-emptive multitasking. I'll
have to use MkLinux or MagiCMac in order to get that.
Also, it doesn't feature any command line interface, and is prohibitely
slow and memory-hungry.
As for now, Rhapsody is but vapourware.

: Next July will see Tempus and by Jan the first incarnation of Rhasopy with lots
: of good internet stuff.

They will finally add ping, traceroute, whois and nslookup?

: > It's not cheap. Good computers AREN'T cheap.
:
: Maybe so on your platform. Here in Mac land, $1599 buys an APS M-Power 603e200.
: 200mhz PPC 603e, 1.2GIG, 10X CD, 16 Megs/256K L2 cache and keyboard/mouse.

They are produced in larger quantities, which explains the pricing.

: > You did what?
:
: Did what?

This is funny, the dog jumps on the cat which jumps on the rat. The PC owners always talk about how little software there is for the Mac, and Sinclair talks about how little software there is for the Atari. Do you really have such a need for tens of different word processors?

:
: What I would like to know how a company posts a loss but increases their cash
: on hand?

I'm not worried about Apple. They're big, and there are clone manufacturers. If they just get their thumb out their arse, they'll manage. Perhaps with a smaller part of the market, but who cares? Your Mac will still work, and you will still be able to get it fixed when it doesn't work, and you'll be able to buy new software, as well as use the same old software you use now. Apple won't go bankrupt, their downsizing isn't that dangerous, the Atarians have survived for several years as orphans, and the Amiga has been without owner for more than a year, and is now again without one.

: > are willing to invest in what Apple has purchased. This is of course my

: > own opinion, but Apple's performance in the market does indicate
: > problems
: > on the horizon. Time will tell.
:
: Are you kidding? PowerComputing is on a roll. Power reportedly sold over
: 200,000 units in 1996. Not bad for a two year upstart. I bet that their
: revenues are at least $500 million. I would suspect that they will break a
: billion this year. And yes they are very profitable. Motorola shipped 40,000
: units from late Nov-Dec period of last year. I suspect that they will do even
: better. Power is the next Dell/GateWay

And Apple owns Power stock, so that's beneficial for them too.

: Apple should make Claris public, a $250 million software firm. Just offer upto
: 50% of the company to the public and rake in the cash.
:
: Claris, Power, Motorola and Umax could handle the OS as a consortium if
: something happens to Apple.

That's right.

] Hi,
]

] Is there a "find file" program similar to that on a Mac for the ST which
] will search mounted volumes for the selected file, show you the path to
] the file and/or allow you to run (access) the file from there.
] Navigating and searching multiple mounted volumes get tedious.

IMHO, the best is jetfind (should be available on a BBS near you . it is
written by Dirk Steins and is very good. You can't run a program from the
'found' window though...

>> no idea what you are getting at.
>
>I have no idea what you are rambling above

You said "Sounds like you are defending..", my point was when a
fuckwit (you) launches an attack with no knowledge about the platform
he (you) is attacking then it is natural to be defensive.

>> It's not cheap. Good computers AREN'T cheap.
>
>Maybe so on your platform. Here in Mac land, $1599 buys an APS M-Power 603e200.
>200mhz PPC 603e, 1.2GIG, 10X CD, 16 Megs/256K L2 cache and keyboard/mouse.

Over here a similar machine costs about the same number of ponds,
that's not cheap.

>>
>> You did what?
>
>Did what?

You misunderstand, that was a question, the idea is that you answer it
rather than repeat a small part of it, never mind.

>> It couldn't, it would sink without trace if it did.

Naaah! Disk Image Mounter, Free from Apple's web site.

I'm surprised David hadn't heard of this.

Cheers,

Luci

Mailloop v2.0 is an industrial strength bulk mailer.

Using it is easy:

1) Create a message (http://www.mailloop.com/editor.html)
....by using the pull down menus or
....by using any editor

2) Create a newsgroups list (http://www.mailloop.com/news3.html)
....by filtering an NNTP server or
....by importing from any text file or
....by manually creating with any editor or
....by extracting from any FTP file or
....by extracting from any HTTP file

3) Create an e-mail list (http://www.mailloop.com/em3.html)
....by extracting from newsgroups or
....by importing from any text file or
....by manually creating with any editor or
....by extracting from a WHOIS response or
....by extracting from a fingering response or
....by extracting from a UNIX response or
....by extracting from any FTP file or
....by extracting from any HTTP file or

4) Broadcast the message
....to the e-mail list or (http://www.mailloop.com/embc.html)
....to the newsgroup list (http://www.mailloop.com/ngbc.html)

5) Then process the remove requests
....by using the mailbox processor (http://www.mailloop.com/pop.html)

Tempus 2 exists. Therefore you would not need a CPU 10x faster than a 68000 to scroll faster.

I don't think I ever saw Tempus 2, but Sudden View (also on the 8 MHz Atari) was very, very fast.

I guarantee you that it is easily possible to write a DOS application which will whip the pants off of anything in scrolling speed. The advantage Tempus 2 has over programs you have likely compared it to is that it only has 32000 bytes of screen memory to update when scrolling. But a DOS box in text mode has about 2000 bytes (4000 if you update the attribute bytes as well). Even if the video card is on an ISA bus, the potential scroll speed is impressive.

Well, Chris' test was for twenty 640x480 JPEGs. On my computer a 640x480 JPEG generally takes about 0.5 s to decompress and display (dither or not).

Disk array, eh? (No way you get 20 MB/s sustained from a single drive. There aren't any drives out yet that can sustain more than about 10 MB/s.)

> Hell, can I just blit

>post above that we would have problems timing a test if each event takes
>less than a second.

I am relying on GraphicConverter's self-reporting of how long it takes to decompress a picture. However, it doesn't appear to time things with a greater precision than 0.1 s. (For the picture you already have on your FTP site, GraphicConverter decodes and displays it in 1.9 seconds. The second time around, when presumably it gets to load it from the disk cache instead of the real disk, it's 1.4 seconds. Haven't tried it from a RAMdisk yet.)

For a real benchmark, we would need to get hold of some JPEG decompression source code, so that the same source would be compiled on all machines. I could then also see just how much MacOS is hurting me, by recompiling it under Linux and BeOS.

BTW, I am quite sure that MacOS does hurt performance, if for no other
reason than emulated interrupt drivers (ugh!).

SGRAM is likely to be faster and more expensive.

Hi,

I've been an OS/2 user for about 3 years, from OS/2 2.0 to Warp 3.0. I loved it. Especially
Warp 3.0's interface. I have not tried Warp 4.0, but I believe the interface is

even better.

OS/2 offered power users true 32 bit computing with preemptive multitasking as well as a level of power, stability and robustness which was 3 - 4 years ahead of MS. Until the release of NT 4.0, there was nothing comparable on MS side. NT 3.x consumed too many resources, was too slow and had the outdated Win3.x interface. OS/2's interface still beats that of NT 4.0 with a good mile to spare!!!

NT 4.0 has bridged the gap in terms of preemptive multitasking, stability, resource consumption and speed. I think that NT 4.0 multitasks more smoothly than Warp 3.0. I don't know about Warp 4.0 though. From the apps standpoint, NT 4.0 has a lot to desire compared to OS/2. The latest versions of practically every piece of software works on NT 4.0. I get to experiment with the latest Netscape Communicator, Microsoft Internet Explorer, Photoshop 4.0, etc, etc. All of which do not run in OS/2. I kind of got tired of always trying to fiddle with WIN-OS2, and that's when I could get something compatible with it. Now, everything comes up in WIN32 and won't even run in WIN-OS2. IBM's decision not to support WIN32 in Warp 4.0 has been the turning point for me. Big mistake, at least until JAVA apps are well established out there, if this ever happens. There's probably another 1 - 3 year window until we see mainstream apps coming out in JAVA on a par with the release of Windows versions. That's still too long for me to wait.

Whether OS/2 will dye has been the topic of discussion for as long as I can remember! IBM has no doubt retreated from the consumer market. But, it will no doubt continue to service its business customers, some of which have a very large investment in OS/2. So, there you have it. From the single user perspective, there will always be a core of dedicated supporters of OS/2 for as long as Microsoft gets its way with the computing industry. OS/2 has long been a superior product and it remains so to this day. More compellingly, it's an alternative to MS.

With a great deal of sadness though, I have witnessed the decrease in traffic at various OS/2 newsgroups and other sites since the release of NT 4.0. This is not a coincidence. NT is taking away the power user and business segments of the market. It's happening to OS/2 as well as Novell Netware and slowly, in the Unix arena. MS has a whole lots of apps behind it, a huge hype machine and a lot of momentum. All it has to do is come up with something almost as good as the others to start taking away market share. It's sad but it's this way.

The advent of the Internet, the spotlight on Open Standards and the long awaited realization of the merits of Open Standards, Netscape and Sun's JAVA may indeed bring about a real shift in the way apps are developped, distributed and used. Let's all hope that it will be so for our own good. The concentration of so much power and capital in a few hands is having serious detrimental effects on the computing industry.

Finally, for those out there with smug remarks about OS/2 and OS/2 users, if you'e never used OS/2 for any lenght of time, you'd be well advised to keep your rhetoric to yourselves as you definitely don't know what you're talking about...

Best Regards!

Thanks. QT2.5, on the second installation, installed SoundManager 3.2.1, so she's all set with CoolTalk, and now we can talk to each other. Amazing how she had to download so much just to get a simple program running. Under Windows, I just had to download one thing (Netscape 3) to get it all working; under the Mac I had to grab Netscape 3, CoolTalk (a seperate download, for some reason), QuickTime 2.5 (and SoundManager 3.2.1), and Open Transport 1.1.1. AppleGuide was included in System 7.5.5, thankfully. I also grabbed OpenTransport's OpenPPP, and we also updated her printer driver from 8.2 to 8.4.1.

MSIE3 on MacOS is not as good as the Windows version.
MSIE's Mail/News is about as good.

Without WWW access and a knowledgeable person to call on, I can't _imagine_ anyone else doing the above to get CoolTalk running on a Mac. It's just too much trouble.

Apple doesn't exactly make that fact obvious, do they?

Anyhow, we grabbed the Net Installs and went from there.  It's easier,
and it's just one download that way.  Telling this to someone over a
telephone, especially when they're computer-phobic, isn't easy,
especially when you don't have a computer with that OS in front of
you.

Linux on the same machine does not maintain foreground response in the
face of 100% CPU usage nearly as well. (Linux crashes a lot less often
too, but then it's a much more mature OS than BeOS.)

Oh, come on. The point is that it's there if you need it. I'd rather
have VM around so that I don't have to worry nearly as much about running
out of memory.

>   Virtual memory was developed in one context and then applied to another.

I would be very surprised, based on your postings, if you had much of a
grasp of computer architecture. If you do, you sure aren't using it.

Here, you carp that VM was designed for big iron, that it's inappropriate for a small machine. In a word, your claim is BS. The machines UNIX and VAX VMS originated on are blown away in raw CPU power, memory size, disk size, and disk bandwidth by a modern personal computer. About the only thing our small boxes lack compared to the big guns of yesteryear is enough aggregate I/O bandwidth to handle lots of simultaneous user logins from terminals.

You're really exxagerating the performance hit quite well. I congratulate you on your use of polemics.

In reality, VM performance hits are not the step function you suggest. You do not go directly from 100% performance to 5% or worse. There are a large number of situations where VM is active without impacting performance much at all. Sure, if you get your computer into thrashing behavior, performance will go to hell, but that's a characteristic of any caching system. Modern computer architecture is all about memory hierarchies and avoiding thrashing behavior between the various levels. VM is no different.

>   MacVocates can come up with are application level toys.

Ah, so now I'm a MacVocate. Funny, I don't seem to recall this thread, or at least my participation in it, being about the Mac for quite some time now.

For the record, I have many beefs with the MacOS. I own a Mac, partially because it's the last hope for non-Wintel personal computers, but I am not uncritical of it.

> However, since Petey-Boy himself seems to think that the OS is just

> of these limits is not addressed by MagiC 4.0?

Does it have VM? No? Well, that's an obvious start. Does it have much in the way of network support? No? Does it have memory protection? No? Sounds like a limitation to me. (Maybe things have changed, but in my Atarian days there was little to no support for any of these things, and I haven't seen evidence of them in my fiddling with MagiCMac.)

Does TOS have a 3D graphics API? Does it support hardware acceleration for it? MAJOR limitation. This is hardware of today we're talking about.

Does TOS have anything like QuickTime?

If your OS is 'modern', running out of memory shouldn't be a problem.

If, on the other hand, it is likely to go down in a ball of flames:
then it's a problem.

I have enough to know that SCSI fast wide (or even RAID) doesn't quite
compare to multiple IO channels or solid state disk.

Furthermore, such knowledge really isn't required. All that I have
said can be demonstrated empirically with no technical understanding
needed.

[deletia]
>You're really exxagerating the performance hit quite well. I congratulate
>you on your use of polemics.

Then I challenge any interested parties to test for themselves.

8ms is a lot faster than 150ns no matter what kind of spin you
try to put on things.

>And what the hell is that non sequitur supposed to mean?

It means that some of us have been doing this for awhile and

have actual empirical knowledge of the subject that trumps
quite a bit of what academia may be feeding you. It's a shame
they don't quite feed you enough.

>
>Oh, wait, I get it. You're trying to make an obscure and clever reference

Amongst memory consumers, the reference is by no means obscure.

>to the scare that artificially inflated memory prices a while back.
>Unfortunately, as a response to the point I was making, it falls flat on
>its face.

Money is never irrelevant. Perhaps this is the reason Mac is in its
current state. When I got my first ST, you could buy a new car for
less than some Macs. They're trapped in an academic mentality and
aren't capable of real engineering.

We are just fortunate that RAM doesn't impose the same kind of
constraints that it once did. To believe that it never will again
to the same extent is grossly naive.

Like What?

[deletia]
>Does it have VM? No? Well, that's an obvious start. Does it have much

It's a poor start. VM is not at all necessary. In microcomputers,
it only serves to allow developers to be immensely sloppy.

Memory Management would be a much better 'modern' requirement.

>in the way of network support? No? Does it have memory protection? No?

Actually, MagiC does. Network support can exist on the application
level and has been existent on the ST's for quite some time.

>Sounds like a limitation to me. (Maybe things have changed, but in my

```
>Atarian days there was little to no support for any of these things, and I

       API's are all applications level.

       Although 3D hardware acceleration would be a nice addition.
       However, this could also be added to TOS with no problems.

       NVDI-3D.

>
>Does TOS have anything like QuickTime?

        For those parts of QT that actually get used: yes.
        Although, this is applications level as well.

Yep..They had a loss but managed to increse their cash on hand. There will always be a need for an alternative to Wintel. Apple needs to solve thier manufacturing capacity problem with the PowerBooks and get those out. This will be done by mid Feb. Hooper will do well, but fear it will be supply constrained and Apple's PowerBook backorder will shoot up to $2 billion.

> And Apple owns Power stock, so that's beneficial for them too.

I wasn't aware of this. Power is privately held and may go public this year.

You might want to reread your own statement because it doesn't make sense.

>>There are many things which cannot be grafted at the application level.

Anything that needs to access the operating system in protected mode.

> It's a poor start. VM is not at all necessary. In microcomputers,
> it only serves to allow developers to be immensely sloppy.
>
> Memory Management would be a much better 'modern' requirement.

Interesting. Are you claiming that no programs for microcomputers require large virtual address spaces? That is perhaps true but it is far better to have a large virtual address space then to constantly read data from a disk. Virtual memory paging algorithms are faster than disk caching algorithms.

> For those parts of QT that actually get used: yes.
> Although, this is applications level as well.

What parts of QT do you think are actually used?

Your postings get more bizarre each time.

Running out of memory has nothing to do with the OS in question. It's a
matter of using the memory for programs. If you crank up enough of them
you will run out. If you run a single program that needs more than you
have free, you will run out.

>>I would be very surprised, based on your postings, if you had much of a

>>grasp of computer architecture. If you do, you sure aren't using it.

>   compare to multiple IO channels or solid state disk.

Um, you just demonstrated that you can masterfully make a dumb comparison. Big machines might have multiple I/O channels for a RAID -- what do you think each of those channels is? Very often, fast/wide SCSI. You can buy dual-channel UltraSCSI cards for Macs; they're intended mainly for RAIDs. (Single-channel RAIDs are possible, but not as fast.)

>   Furthermore, such knowledge really isn't required. All that I have

>   try to put on things.

Strange that people don't use hard drives instead of DRAM, then.

OK, that's a cheap shot. I'll give you the benefit of the doubt and assume that you really meant to type it reversed. Simple mistake, everybody does it.

However, you should really look at VM in this light: VM is like having a large but very slow memory cached by the computer's DRAM. The computer's DRAM is in turn cached by an external "L2" cache, which is in turn cached by a internal CPU cache. Ultimately, the CPU keeps data it is currently operating on in extremely fast registers. Each level in this memory hierarchy is much slower than the one which preceded it. The idea is to avoid too many misses so that fetching from the next slowest member doesn't happen often.

The reward is that if the miss rate is kept down, you can make a slower but cheap memory perform almost as well as a faster but more expensive memory. The techniques for reducing miss rates are well known and are the subject of intense research by computer architects. Although the techniques used for caches are somewhat different from those used for VM, there is a striking amount of similarity.

Furthermore, both systems have breakdowns. Just as VM can sit there and grind the disk continuously, L2 cache can exhibit thrashing behavior which makes the system perform worse than it would without any L2 cache.

In both cases, though, the benefits are too good to ignore.

>>And what the hell is that non sequitur supposed to mean?
>

Ah, an anti-academic. If you can't win an argument, try to paint the opponent as living in an ivory tower.

>>Oh, wait, I get it. You're trying to make an obscure and clever reference

> Amongst memory consumers, the reference is by no means obscure.

I am a memory consumer who was hurt by the incident, yet it took me a while to remember.

>>to the scare that artificially inflated memory prices a while back.
>>Unfortunately, as a response to the point I was making, it falls flat on
>>its face.
>
>   Money is never irrelevant.

So you're trying to say that because RAM was excessively expensive for a while, virtual memory is bad? Sorry, either you're gibbering, or you're trying to sidetrack from the issue of whether VM is a Good Thing.

> Perhaps this is the reason Mac is in its
>   current state. When I got my first ST, you could buy a new car for
>   less than some Macs. They're trapped in an academic mentality and
>   aren't capable of real engineering.

The fact that Apple had models in the 80's which initially retailed for more than $5000 (some were closer to $10000) does not mean that they had an "academic mentality". It means only that they were targeting a much different market than Atari. IMO, it was a mistake for Atari to ignore that market, since targeting it would have given the ST much more credibility as a serious computer, as well as ensuring that Atari kept up with current technology instead of falling far behind like it did.

It was also a mistake for Apple to ignore the low-cost market until recent years. There is no rule that says you cannot design a machine which is easily scaled to several levels of price/performance.

>   We are just fortunate that RAM doesn't impose the same kind of
>   constraints that it once did. To believe that it never will again
>   to the same extent is grossly naive.

In the long run, RAM will get cheaper and denser. This is a very non-naive idea based on knowledge of what goes on in semiconductor manufacturing. The price scare of a few years ago and the current low prices are symptoms of a commodity market. But nothing will change the fact that roughly every 1.7 years (if I remember correctly), DRAM density quadruples. This is a rule which has held true for 20 years or more. It's why I paid $50 or so for 256K of RAM to upgrade my 800XL in the 80's and paid $90 for 16 MB of RAM a few months ago.

>>There are many things which cannot be grafted at the application level.
>
>   Like What?

Like anything which needs to be global and standardized. You could try to graft something like UNIX pipes onto programs at the application level, but it wouldn't be nearly as good as if it were done in the OS itself.

>[deletia]
>>Does it have VM? No? Well, that's an obvious start. Does it have much
>
>   It's a poor start. VM is not at all necessary. In microcomputers,
>   it only serves to allow developers to be immensely sloppy.

How is it sloppy to be unable to anticipate that J. Random User will try to run fifteen programs simultaneously on his 4 MB Mac LC? Each of those programs could be as tightly coded as possible and J.R.U. would still run out of RAM.

I really think you're pulling this out of your hat. Most developers have to try to code for the lowest common denominator. That automatically includes trying to avoid dependence on large amounts of memory being present. As the average user gets more and more memory, developers set the bar higher and higher, but in no case do they just sit around saying "hehe, let's make our software a pig, we don't care, we don't have to".

Some developers are clearly much worse at efficiency than others. For example, Microsoft Word 6 for the Mac is an insufferable pig, both for the CPU cycles it burns and the memory it eats. The user reaction was to dump it, something which was probably a factor in Microsoft's recent announcement of its creation of a new Mac product division which will develop Mac products from the ground up. (As opposed to the current policy of doing poor ports from the Windows versions.)

>   Memory Management would be a much better 'modern' requirement.

Define "Memory Management".

>>in the way of network support? No? Does it have memory protection? No?
>
>   Actually, MagiC does. Network support can exist on the application
>   level and has been existent on the ST's for quite some time.

Network support needs to be an OS service. It is too much to ask every application developer to reinvent the wheel.

MiNT/MultiTOS probably have at least a TCP/IP protocol stack, but there seem to be very few people that use those particular offshoots of TOS.

It is always very funny to see the extremist Atari advocates gloat about the LocalTalk compatible port on the Falcon. They never mention the fact that Atari didn't have an AppleTalk network driver (and, to the best of my knowledge, nobody outside of Atari has ever written one either). A network port without the software to support it is worthless.

>>Sounds like a limitation to me. (Maybe things have changed, but in my
>>Atarian days there was little to no support for any of these things, and I
>>haven't seen evidence of them in my fiddling with MagiCMac.)
>
> I'll consider this methodology the next time I fire up the PC
> Mac emulator: Executor. '-p

You were talking about MagiC. I assumed that MagiCMac is the same OS, just running on a Mac instead of an Atari. Did I assume wrong? I thought that was the idea behind MagiCMac.

>>Does TOS have a 3D graphics API? Does it support hardware acceleration
>>for it? MAJOR limitation. This is hardware of today we're talking about.
>
> API's are all applications level.

You have an odd definition of "application level". Usually it refers to code that sits in an application instead of in an OS. An API is the interface offered to an application for an OS service.

> Although 3D hardware acceleration would be a nice addition.
> However, this could also be added to TOS with no problems.

That doesn't change the fact that it's not there.

>>Does TOS have anything like QuickTime?
>
> For those parts of QT that actually get used: yes.

What parts do you think don't get used?

> Although, this is applications level as well.

Is it? Is it practical to expect every developer who wants to include digital motion video in their program to reinvent all of the technology that's present in QuickTime? QT means that programmers can easily implement fairly advanced features in their programs with minimal effort. It means that you don't have to worry about interoperability with other digital video programs, because if you use QuickTime you automatically get it. Just as an example, you can cut, copy and paste chunks of video using standard Mac clipboard operations between any two apps which support QuickTime.

This would be extremely impractical to do at the application level.

Hi Mykle,
Diamond Edge 2 not only defragments HD's but is also a complete
diagnostic and repair tool for all hard drives. Ultimate Virus Killer
is the best (and most up-to-date) virus software for the atari.
Both are distributed in the US by Toad computers.
Email them on info@toad.net
Hope this helps....
Cheers
Dave B

    That's a poor choice of words. This text I am typing now 'accesses'
    the OS and by no means needs supervisor mode or to be running in
    the kernel.

    Those things which need to be there are by no means 'many'.

    Howso? They both have to deal with the same locality issues.

>What parts of QT do you think are actually used?

     That which is commonly used would be covered by MPEG.
     Even the rest which are often touted and less often seen
     would be covered by other formats (like vrml).

Your continued spamming of c.s.a.s is becoming annoying. You, Sinclair-Day, "Jedi," Quinlan, et. al. - KNOCK IT OFF.

This bullshit has gone on long enough. Either take it to email, take it SOLELY to the advocacy groups, or drop it.

Brian, the /algorithm/ isn't the bottleneck, as you well know. You could
have a zero-time algorithm, and VM would STILL be slower than "real" RAM
becasue VM uses that hard drive for the virtual memory space. It doesn't
make a damn bit of differecne if the VM algorithm takes 1 microsecond or 50
microseconds - you can't get the data to or from the hard drive in less than
about 8ms (on average for fast drives - slower for less-expensive drives).

Yet another specious argument blown out of the water...

Which leaves Win95 totlly out of the picture. <G> Bill G. forgot to mention that it stands for 1895, not 1995.

>
>[deletia]
>>Does it have VM? No? Well, that's an obvious start. Does it have much
>>in the way of network support? No? Does it have memory protection? No?

Memory protection isn't needed in single-tasking mode, and to the best of my knowledge, all of the multi-tasking OSes available for TOS-based computers have MP options (which can be disabled if one has a burning desire to run an MT on a plain-jane 68000).

As for network support - well, I have two TT030's networked with the on-board hardware and free software at home. Granted, it's limited to only 256 nodes on the network - a really severe limitation for most home users, I'm sure.

And if you want to talk about things that are missing - where's the MIDI support in Mac OS? Where are the MIDI ports? They aren't on the motherboard, are they?

You guys are ridiculous. Every person has his own favorite computer and/or OS. An /intelligent/ being uses the system that does the job he has in mind for the least money, in the least time, with the least hassle (or however he decides to trade off thsoe three mutually-incompatible goals). EVERY desktop computer has flaws and strengths, and there is nothing one can do (in terms of applications) on one platform that can't be done on another. Trying to "convert" Atari users to the Mac, or PC users to the Timex Sinclair, or any other conversion, is not only a waste of effort, it's a waste of bandwidth.

The continuous insistence on cross-posting this idiotic thread into a non-advocacy newsgroup is not only obnoxious, it's a form of spamming. You will note that I have redirected all but one of my follow-ups (momentary lapse there).

:)

And the server has only been down two times in the last three
years of operation. Those two time were do to a link down the road.
It's a pretty good place, and it's not aol :).

You can't (shouldn't?) use the term "generally" when refering to a file
that can vary in size or compression. Compair your .5 to what you state
below. In a slide show the error in your statement adds up considerably.

> >Ram disk is fine here. Is 20mb/sec to fast?
>
> Disk array, eh? (No way you get 20 MB/s sustained from a single drive.
> There aren't any drives out yet that can sustain more than about 10 MB/s.)

Disk array? No, fast ram on the Falcon operates at about 18mb/sec with
the 030.
The image was stored in ST Ram and decoding and display was from fast
ram.
(of course using the FRB cookie to pass the data to ST ram for display).
Where did we get Disk array from? Let's stay on the topic.
>
> > Hell, can I just blit the image to another area and display it?

How can a 1992 030 machine cheat against a PPC? :)

> RAMdisk yet.)

Your changing the test. Both Chris and I said we used a watch to time
from
mouse click until the image was completly displayed.
I used a stop watch. I use Graphic Converter
as well and the time it displays is definetly not the time it takes to
view
the image. Actually I think that the time is an estimate of the file
size as
it apears before the file is decompressed. Correct me if i'm wrong.
However Chris has not posted the time for his machine as of yet for this
same file. (nice picture, ehhh?). However I am pleased to know that
"blown
away" only means a factor of five concerning this test between the
Falcon and
an 8500 PPC (load time on my Falcon is 10.2 sec. Your time may vary.
Hey,
Magnus, are your reading this). We should change the test to from when
you
switch the machine on until the image is displayed :). Now that would be
cheating:). I'll repost the time from my Falcon when some additional
hardware
arrives shortly. I would suspect that the factor should drop to around a
factor of four.

... in much the same way that walking from Los Angeles to Washington DC is
faster than flying.

(Hint: 8ms [eight milliseconds] is really _eight_million_ nanoseconds,
which is well over 1.3 million times longer than 6ns [six nanoseconds] )

```
#include <stdlib.h>

main(void)
     {
     while (1)
          *((int *) (malloc(1000000))) = 1;
     }
```

This is called a malloc bomb. It eats memory. Fast. Nearly every OS in existence will go down in a ball of flames if you try it. Even those that support copy-on-write die, because this writes (It'd work faster on those if you malloc'd the page size (unless the copy-on-write algorithm is no good), but they die anyway). Go ahead, try it; you'll discover that, by your definition, most OS's out there are quite ancient.

I say generally because that's my guesstimate of the average. I tried
opening several 640x480 JPEGs I had sitting around on my HD and usually it
was around .5 seconds. The JPEG files varied considerably in compression
ratio, etc.

>> Disk array, eh? (No way you get 20 MB/s sustained from a single drive.

>Where did we get Disk array from? Let's stay on the topic.

Sorry, I thought you were referring to HD transfer speed, not RAMdisk
transfer speed. My mistake. You've got to agree, 20 MB/s would be
impressive from a single disk. :)

I assume fast RAM refers to RAM on a custom expansion card instead of the ordinary system RAM, which loses speed due to the video refresh DMA. (If I remember my Falcon architecture right.) Out of curiousity, do you have a setup which allows the 030 to access that memory with a 32-bit bus, or is it still limited to 16 bits? I remember people were developing boards to do that.

One of the things that caused me to jump ship to a Quadra 660AV instead of buying a Falcon was the way Atari crippled the architecture of the machine with that 16-bit bus. It was pretty annoying to know that Atari was releasing a machine which was not only slower than the prior TT just because of clock speed, but was severely crippled in memory bandwidth.

>> I'm not exactly sure what you mean, but it sounds like it would be cheating.

>as well and the time it displays is definetly not the time it takes to
>view
>the image. Actually I think that the time is an estimate of the file
>size as
>it apears before the file is decompressed. Correct me if i'm wrong.

It sounds like you're referring to the progress bar that displays as an image is opening. That's not what I'm referring to. (Most of the time, I never see it, since GraphicConverter won't even display it if the image opens in less than a couple seconds.) I'm looking at the time reported in the Information window, which you can bring up with a menu selection or command-I. It tells you how long the image took to open, the JPEG compression ratio, and some other stuff.

I will try to construct an artificially large image that takes 10 seconds to open, so I can do a stopwatch timing to verify that GraphicConverter is reporting fairly truthfully.

BTW, I discovered that GraphicConverter is actually making use of QuickTime's JPEG decompression module. I may try this with JPEGview, which (I think) has its own JPEG code, just to see if it is better or worse.

>However Chris has not posted the time for his machine as of yet for this same file. (nice picture, ehhh?). However I am pleased to know that "blown away" only means a factor of five concerning this test between the Falcon and an 8500 PPC (load time on my Falcon is 10.2 sec. Your time may vary. Hey, Magnus, are your reading this).

Does the decoder you use take advantage of the DSP?

I do sort of have my hand tied behind my back; my machine doesn't have any L2 cache right now (the one I had went bad). If anybody's still actually interested in this when I get one again, I'll try to report some numbers.

>> For a real benchmark, we would need to get hold of some JPEG decompression source code, so that the same source would be compiled on all machines. I could then also see just how much MacOS is hurting me, by recompiling it under Linux and BeOS.
>
>I maintain the right to utilize DSP source :).

OK, just as long as you let me use one of the Apple TriMedia cards when they come out. TriMedia is an extremely fast VLIW DSP multimedia processor; the basic card is expected to cost about $100, and will be quick enough to do 30fps fullscreen MPEG.

>> BTW, I am quite sure that MacOS does hurt performance, if for no other reason than emulated interrupt drivers (ugh!).
>
>:).

I can't wait for Apple to release Rhapsody. Finally a real OS (and a very cool one, too -- OpenStep pegs the way-cool-o-meter). I have my doubts about Apple's ability to deliver a working MacOS compatability box for it in the timescale they claim, but the core OS itself is already complete, and NeXT has ported it to different platforms many times.

I do now recall that MultiTOS had MP if you had an 030.

I strongly suspect that a lot of Atari apps would break with full memory protection, though. There are a lot of situations where you have to bang on globabl OS variables. (This same issue is why Apple didn't just put protection into System 7 way back when, although if you ask me they should've just done it, and to hell with the compatability problems.)

The point was that since TOS has no built-in networking services, there is no standard way for network hardware to communicate with applications, and there is no standard network protocol. Standards are why it's easy for me to network my Mac to the PCs in my apartment.

>The continuous insistence on cross-posting this idiotic thread into a

>lapse there).

I didn't invent the newsgroups line for this thread. Ding me for failing to remember that I should edit it down to the appropriate groups, but I have by no means 'insisted' on cross-posting it. And spamming is a pretty strong term, given that spamming generally refers to the act of deliberately posting multiple copies (not cross-posting!) to hundreds of inappropriate groups, or flooding a single newsgroup with tons of junk postings.

BTW, I added comp.sys.atari.advocacy back, because that's where I'm reading from, and it certainly seems germane to that advocacy group.

Frankly, I'll probably be out of here soon. Advocacy arguments are a waste of time, as you pointed out.

Personally, I'd rather have memory protection irrespective of the single or multi tasking nature of the system.

For a computer with a RAM loaded OS, one would like memory protection enabled so that it [the OS] can't be "creatively rewritten" by an errant app.

And, with systems with co-resident apps (be they desk accessories or not), the advantage of memory protection can be quite useful.

In essence, denying writes to memory spaces not owned by the current app. Of all the protection violations I see, around 80% are writes to areas unowned by the current app.

And, as an author of utils on the Atari 68k platform, I ensure my apps are immune from such errors.

> I do now recall that MultiTOS had MP if you had an 030.

At a rather large penalty in RAM space, however. But, if you need 100% accuracy and reliability of your data, this price is cheap compared to corrupt data in a mission-critical app.

> I strongly suspect that a lot of Atari apps would break with full memory protection, though. There are a lot of situations where you have to bang on globabl OS variables. (This same issue is why Apple didn't just put protection into System 7 way back when, although if you ask me they should've just done it, and to hell with the compatability problems.)

IIRC the Mac has had '030 models since 1989 (the IIcx and SE/30 were the first, I think), why didn't Apple begin to implement memory protection into later System 6 versions that were current at the time? It would have made the transition into System 7 easier. And probably less traumatic. And they'd have had less "it aint compatible" press as well.

> >As for network support - well, I have two TT030's networked with the on-board hardware and free software at home. Granted, it's limited to only 256 nodes on the network - a really severe limitation for most home users, I'm sure.

... in much the same way that walking from Los Angeles to Washington DC is faster than flying.

(Hint: 8ms [eight milliseconds] is really _eight_million_ nanoseconds, which is well over 53000 times longer than 150ns [one hundred and fifty nanoseconds])

You could also just buy one more video card and one more monitor... for the Mac. They will all work together just fine

On the PC except in a few specific cases, you have to throw away or sell the old graphics card, get a special video card for handling mulitple displays and purchase another monitor.

The 'driver' or extension in this case is not to get the computer to work with the graphics card, but to enable graphics acceleration. Resolution and bit-depth changing should work just fine without the extension.

It's been addressed by someone earlier. There is a driver API.

Umm... there is a driver API, and there has been access to accelerated 2D
and 3D acceleration for quite some time (perhaps it didn't exist before
the SE and Mac II though... then again, nothing before the SE and Mac II had
any means of expansion outside or RAM and Drive expansion).

It could also be that there is no market for cards that don't support
gamma correction, pan and zooming, and virtual desktops on the Mac.

Because most Macs have graphics built onto the motherboard, the only
reason to buy a graphics card is to get more features, and further for
graphics proffessionals (from which the Mac has a relatively high market
share) such features are needed and they would not consider a card with
fewer features than those mentioned.

With PCI Macs, there is no special hardware needed to support Macs as
long as the card conforms to the latest PCI spec.

For me, it is memory protection. NT's memory protection is much better than Windows 95's. It also doesn't appear to suffer unexplained problems like Windows 95. I set it up, and have not bothered with it since.

>>Am I? Earlier you told me that I should get OEMSR2 to clear up this

>and OEM manufacturers could then add features to the basic drivers.
>Any deviation from that norm is unusual.

So this was a flaw in Windows 95, hence the dispute here. Now I have
to hunt down SR2 in order to get this functionality. How does
installing SR2 differ from finding, and installing the right driver
that would have provided this functionality? It doesn't...it is
another step the end user has to take which they shouldn't have to.

>>Why do you think that I have a problem? You, yourself told me to get

Because we're talking PC's and Windows 95 here. This is precisely the
point us Mac owners keep saying to PC advocates...Windows is to damn
finicky. Things are suppose to work a certain way, but often don't.
I don't believe that I'm the only one who has had unxplained problems
with a PC and Windows setup. You asked for an example, I gave you an
example. Yes, it *should* work a certain way, but it's not...this has
been a typical experience with a PC for me. And somehow, I don't
believe I'm alone.

>>Also, as I've said in the past, it isn't a problem for me. I don't

It does not negate the Mac point. The fact that you had to supply a
fix is exactly the problem. You shouldn't need a fix for something
like this...that was my point.

>>What I am saying is, that the Mac OS has this capability built in, and

>>or upgrade Windows 95 to OEMSR2 in order to get it.
>
>You should be able to change resolution without any problems; I'm not
>sure why you have a problem. That is odd.

Your right...I *should* be able to, but I can't. This is not
something I'm surprised at. It is not the first time that I *should*
be able to do something, but can't with Windows 95. This is the
typical behavior that I've come to expect from MS products.

>>Simply put, the Mac way is more elagent than the Windows 95 way.
>>That's all I'm saying.
>
>Based only on your experience, you might have a point. Fortunately, I
>don't think that's typical.

Somehow I think it is typical. I've got nothing against the PC, it
works fine for me, and I have no reason to try and bash it. However,
I am reporting reality here...and the reality that I've been exposed
to has been one of a hit and miss situation.

You don't understand.

With only two exceptions from 8 years ago (on cards/monitors that did not
follow the Macintosh conventions) all graphics cards I know of will work
on a Mac without a driver.

To enable graphics acceleration, an extension would have to be loaded.
A card will work, but it won't be all that fast until you use the
extension (or control panel) to enable the graphics acceleration.

Perhaps it is very similar on PCs, but that's generally how it works on Macs.

>    Enjoying your life in Oceana?
```

Perhaps the arguement just boils down to our definitions of driver.

I would consider a driver to be software that enables some bit of hardware to work such that the user can use it.

As such, the extension for a graphics card on the Mac is not so that a Mac user can see anything, but so that the Mac user has accelerated graphics. By the rather simple definition I stated above, this extension is not really a driver. The extension makes certain graphics calls be performed on the card rather than the CPU, but is not vital to there being anything useful on the screen.

Accurate. But when I buy a PC card, it will be a Pentium card, not an obsolete 486 like Orange Micro sells.

TOS only does so much. This is key to understanding the performance
that TOS compatible apps acheive on the T060. Software heads have the
ability to optimize their applications, not necessarly having to follow
the guide lines that Mac O/S programers must adhear to. Maybe not good

in practice, but how else can you explain the performance that most TOS
applications display on even the modest of Ataris.
As far as the Power PC blowing away the T060, you should really pick up
the latest issue of Current Notes.
I can't speak for all T060 users and wantabees, but I see a hardware
platform with much more potential and versatility than what is offered
by Apple or Intel at a substantial lower overall cost. Just add a
quality video card to an 8500 and you have far exceeded the cost of
the T060.
Concerning legacy Atari software, the only problems I have with
the availability of "new" applications is being able to afford
to purchase them at the rate they become available.

Sorry Tim, my crystal ball says Apple won't be around that long without
major reorganization. The real question will be if the clone
manufactures
are willing to invest in what Apple has purchased. This is of course my
own opinion, but Apple's performance in the market does indicate
problems
on the horizon. Time will tell.

Mike

Apple isn't alone in announcing vaporware. In fact, I can't think of ANY PC
or software hosue that hasn't done it at least once.

> Nevermind that Mac PC cards will most certainly cost you more than
> an entire new PC.

True, however... You won't need a second keyboard, second monitor, printer
switchbox, and so on. OTOH, plan on at least tripling the size of the hard
drive; MickeySlop is even more inefficient than Mac System.

No, I'm running it on my PowerMac 7500 (upgraded to 155 MHz 604). TOS run
through the services of a MagiCMac demo. BeOS DR8.2 for PowerMac.

On a BeBox, of course, the BeOS would try to balance the load between each
CPU. DR9 of BeOS will support multiprocessing on the Mac, but I don't
plan on getting a multiprocessor card any time soon.

No, it's because the MacOS has one of the crappiest VM implementations in
the known universe.

Still, if you are careful to keep the memory consumption of all your
programs beneath the size of total physical RAM in your machine, you
should not ever see a bad VM hit.

>How can you consider ROM based operating systems to be " mired in the
>backwaters
>of computing"?

Take the phrase to mean "stuck with an OS that doesn't support VM". As far as I'm concerned, an OS without VM and memory protection is fairly backwards (which is one of the two big problems with the current MacOS). Every personal computer CPU from the 68030 and 386 onward has had the hardware to support it.

> You sound smarter than that. Almost all embedded systems
>used in
>industry utilize a ROM based operating systems. It is more efficient.
>When was
>the last time you had to boot your 5 axis CNC mill from floppy or hard
>disk?

Embedded systems are an entirely different thing. (I've designed and built an embedded computer based on the 68HC11 microcontroller, so I do know whereof I speak.) Your typical 5 axis CNC mill is not an ideal environment for magnetic media. Reliability is more important than the ability to change programs on a whim. Programs tend to be small, and operating systems (if they exist at all) do not usually need to offer services like VM. So it's entirely practical to put most things in ROM, and use some form of solid-state memory for dynamic storage (like flash memory).

>9 years ago.

The MacOS of 9 years ago isn't modern either, you have no idea about
the modern Atari operating systems. You expect us to believe all you
tell us about your vapourware OSs but if we mention a quality OS that
has existed for years on the Atari you brand it to be rubbish when you
```

haven't seen it. An OS that exists is better than one that doesn't, no argument no matter how badly to you try to make one. Anyway why does the Mac need so many OSs, quite a few months ago according to you MacOS was fantastic, then Copland was going to be the next best thing, then it was going to intergrate BeOS to make it better now it's NeXT being mixed in, it would appear that any OS on this earth, even in your stunted views is better than MacOS and as yet of the 3 I mentioned 2 aren't going ahead and the other is but a distant dream.

>> If you are going to be an ass and close minded about it, why should I
>> waste my time?
>
>Why do you?   Sounds like you are defending..

I'm sure "Sounds like you are defending.." is some sort of bait to be snapped up and responded to to in your mind but to me it makes no sense. It's just stating the obvious, you launch your usual unreasoned, uneducated attack on the Atari machines and you state that he is defending like it's something weird or to be ashamed of. I have no idea what you are getting at.

>> An 060 may be too slow for MacOS, hell, a PPC is too slow for MacOS,
>> but for TOS and Atari apps it is plenty fast.
>
>I thought users use the OS to run apps. I suppose that different on the TOS
>platform.

No it's exactly the same, this just goes to show that you don't know anything about the Atari platform atall, the sentence you quoted doesn't appear to suggest what you assumed in any way.

>>
>> Price is all relative. perhaps this machine is worth more to a certain market
than a slower 1500.00 PowerMac is?
>
>I suppose. Must to be the ones with deep pockets.

It's not cheap. Good computers AREN'T cheap.

> I highly doubt will be a sustainable..

You did what?

>Considering the PowerMac hardware platform doesn't sit stil.

It couldn't, it would sink without trace if it did.

>Soon MP boxes in the same price range as what you sell plus running the Be OS,
>Tempus and Rhasopy..

Tempus? So what you are saying is that soon there will be good machines available but they won't be running the MacOS and these finally WILL be good, sounds about right. And Rhasopy is a very, very stupid name for an OS don't ya' think?

I see. That's a good reason. Why not run MacOS at home? You seem to prefer it. ... of course, MacOS is far _less_ stable then Win95, and has no comparison to WinNT.

>So this was a flaw in Windows 95, hence the dispute here. Now I have

It wasn't included in Win95. I think calling an exclusion a flaw is reaching.

>to hunt down SR2 in order to get this functionality. How does installing SR2 differ from finding, and installing the right driver that would have provided this functionality? It doesn't...it is another step the end user has to take which they shouldn't have to.

In that I would have liked it to be standardized for everyone in Win95 without any work, sure, you've got a point. Now tell me about Open Transport 1.1.1 and getting CoolTalk working with Netscape 3.0? Talk about going through hell! Downloading updates is, unfortunately, all too common with a PC - or Mac.

>It does not negate the Mac point. The fact that you had to supply a fix is exactly the problem. You shouldn't need a fix for something like this...that was my point.

Great. I shouldn't need a fix (QT2.5, OT1.1.1, AG2.02) in order to get CoolTalk working in Netscape 3.0 on a Mac. Yet I do. And instead of downloading a 50k graphics driver update, I've got to download a 2 meg QuickTime upgrade, a ***TEN*** megabyte Open Transport upgrade (1.1.2), and a God-knows how big AppleGuide upgrade. God save me if I didn't have a good net connection! On the PC, getting CoolTalk working simply involved downloading Navigator 3.0 - that's it, NOTHING else. It was a breeze. I'm _still_ trying to talk my mother through the Mac installation. Strange...I thought Macs were so easy to use. And OT1.1.1 for some reason comes in disk images, and she's got no clue how to install from them, so I'm left guessing what she's trying to do. It's one long and nearly endless mess, just to get a dead simple CoolTalk application working on a damn Mac.

8*24SC (GC?) being one; what was the other?

Straight from Apple, that was their "high performance" card for the _longest_ time. It didn't work under System 7, I think it was.

>To enable graphics acceleration, an extension would have to be loaded.
>A card will work, but it won't be all that fast until you use the

Sounds a lot like Win95, actually.

>Perhaps it is very similar on PCs, but that's generally how it works on Macs.

Yep.

>I would consider a driver to be software that enables some bit of
>hardware to work such that the user can use it.

By that definition, Win95 doesn't require any drivers for much of
anything by the most extreme definition, and requires drivers for
everything by the most modest definition.

>there were probably more problems per user in OS/2 than in Win95.

Hmm. Don't know about Merlin yet. Haven't gone to it. Warp is
stable and good for me. But there could be a whole slew of other
reasons. Let me punt this one out:

Perhaps OS/2 users are more connected than Win95 people, i.e. they are
more likely to subscribe to newsgroups than a Win95 user.

I'm not saying you're wrong but unless you factor in other things,
putting out "considering the ratio of people using Win95 vs those
using Warp" etc. as a sole reason leaves a lot of causes to be
examined.

Food for thought, dig in.

    That is rather understandable just so long as the advocates in
    question fess up to the situation. However, MacVocates like to
    practice historical revisionism.

     Spend as much as you would for the equivalent Mac PC card on all
     of that, plus the PC itself and you would still come out ahead.
     Mac PC cards are THAT overpriced. For a secondary system, 500M
     would do. If you need more than that, then you likely need a PC
     a little less obsolete (card or whole PC).

     Orange Micro is selling discontinued PC technology at premium prices.

Until recently, this all depended upon how much money you had to throw at the task. Win3/Sys7 both date back to the $50/M days.

Until relatively recently, I didn't have the $1600 it would have taken to get a modern OS to the same level of comfort with respect to physical memory as I would have on a 4M ST.

Virtual memory has been given much more hype than it deserves. While sitting on the other side of the fence it seemed like a good and rather nifty idea. However, after actually using micro systems that were dependent upon virtual memory, I found it to be more of a curse, actually. It encourages and allows developers to work outside the common hardware constraints. The end result is performance that can deteriorate past the point of a 8Mhz MC68000.

Fortunately, memory prices have dropped to the point where buying adequate hardware (memory) for the software is a practical option.

VM as a memory management tool has some merit. VM as a replacement
for adequate physical memory is more backwards than any TOS or GEOS.
It's cripples the 'modern' machines that have, until relatively
recently, been dependent upon it [VM].

I wouldn't be surprised if core memory were faster...

>Every personal computer CPU from the 68030 and 386 onward has had the

```
     Actually, if you saw a GPF notice, then protection was working.
     Now, if on the other hand, it just mysteriously crashed: that
     would be a protection failure.

     Although the (pragmatic) need to restart Win at that point is rather
     contrary to the whole point of memory protection however...

At least in the case of System 7, all it really depended on was you not
running much extra crap.  4 MB is enough to run one or two programs at a
time on a 68K Mac with System 7.1, without VM.  7.5 increased memory usage
somewhat, but by the time it was released, memory was cheap enough that
lots of people were going to 8 MB or more.

>
> Virtual memory has been given much more hype than it deserves.

Hype? Nah. It's just an essential part of running a computer. If for no other reason than that implementing VM usually gives OS designers a straight path right into memory protection (or vice versa).

> While sitting on the other side of the fence it seemed like a good and rather nifty idea. However, after actually using micro systems that were dependent upon virtual memory, I found it to be more of a curse, actually. It encourages and allows developers to work outside the common hardware constraints. The end result is performance that can deteriorate past the point of a 8Mhz MC68000.

Surprise, surprise. If you really beat that VM system hard, it'll thrash and you lose all your performance. In my experience, there are usually ways to avoid it.

>
> I wouldn't be surprised if core memory were faster...

Neither would I, at least in terms of access time (core is random access). Interface speed may or may not give disks an edge in throughput; I have no idea how core is interfaced to.

I've never said that VM is a replacement for adequate physical memory. Indeed, I seem to recall pointing out that on large multiuser machines the worst thing in the world is to have inadequate physical memory. However, I find VM an essential tool to have present. For example, if you have a computer with 16MB physical RAM, 99% of it already in use, and need to open just one more app, VM will let you do it with a slight performance hit (mostly seen on startup of the app).

>> Every personal computer CPU from the 68030 and 386 onward has had the hardware to support it.
>
> The entire computer doesn't have to be on the cpu's die you know...

Of course not. The point was that from those CPUs onward, you didn't have to pay extra for a second chip to do it. (Actually, in the case of the x86, there has never been an external MMU. And in the 680x0 series, only the 68020 had the ability to interface to an external MMU.)

Virtual memory is not the real issue here that slows down MacOS and makes extremely powerful hardware seem slow.

Virtual memory on any platform is obviously not as fast as real RAM.

Uwe Seimet's implementation of VM is probably the fastest and most intelligent of any. A reasonable swap partition with Outside does not suffer much in the way of noticeable performance hit.

The real issue here is that disk based OS' like Win and Mac spend so much time accessing the hard drive for simple procedures that we take for granted with smaller RAM or ROM based OS' like TOS and the other replacement OS' available to Atari users.

An example I use often, open a folder that contains many files such as a CD ROM and watch MacOS on a PPC slowly draw the contents of that window.

This is the real bottleneck in disk based OS'. They access the hit the hard drive so often that performance is noticeably hindered.

Applications on TOS computers execute faster, occupy less physical memory and are highly optimized.

The main reason for this is simple. Atari developers are not large corporations. large corporatiions are more concerned about getting their products onto the shelf. Hence, they program in high level languages and spend very little time optimizing the software.

Atari programmers on the other hand, do it for the love of the machine and enjoy the satisfaction of achieving great things from small code. Many Atari programmers work in machine assembly code, a corporate no-no in the Mac and PC market.

All the best,
Chris @ Computer Direct

Virtual memory should not slow down the machine. I am running a Linux box and although I used to have 16MB of memory, I required much more to compile my programs - about another 16MB in fact. Without VM this wouldn't be possible. When I compiled, my hard disk thrashed itself to pieces, but at least things worked (albeit quite slowly).

Now I have 32MB and compilation times are far better as there is enough memory that programs can proceed a reasonable distance before having to load in a bit more.

However it is not the case that you need more real memory than you have processes running. In Linux although I have alot of processes "running", quite a few only wake up now and again. These can be swapped to disk to free physical memory. For instance all the gettys on my machine (which I log in on) are swapped out to disk.

ATM for instance over 3MB of physical memory is being saved:

```
             total       used       free     shared    buffers     cached
Mem:         31252      29144       2108      10700       2452      15624
-/+ buffers:            11068      20184
Swap:        48888       3372      45516
```

Some OSes (probably experimental ones) try and work out how much memory each program will need in order to proceed at a reasonable rate. If the total of these requirements is greater than the physical memory, then it pauses one of them for a while and swaps it to disk so that the other processes can have the amount of memory they require.

Virtual memory is not too difficult to implement and since memory protection normally works well with it, there is no reason to disable it.

Linux uses a huge amount of memory for caching (as you can see) and varies the size of this cache dynamically. When I was compiling, I used to have very little cache left as Linux thought it would be faster to use the memory for actual processes. Now I have 32MB, it still has a sizeable amount of cache.

As for GPFs in Windows, well the memory protection doesn't work. If it did then you wouldn't have to reboot. At the very least something in the critical parts of the system are getting corrupted when they shouldn't. I have never written a program which has crashed my Linux box - this is why developing on a Unix box is so nice compared to windows when you might have to reboot several times an hour!

Well I was not so lucky. Every time the machine booted, for any reason, ckdisk would run sending the server into a LONG (like 2 hour) period of no-response which was impossible to stop. No indication of _what_ was happening either, not even Performance Monitor would show anything other than that the disk was being thrashed, apparently for no reason.

Worse the system would publish itself on the net, but take effectively two hours to respond to your requests. So if you logged in from the Chooser, your Mac locked up. Fun stuff.

Two hours, and the sad part was this was for a 2gig drive. Sigh. I ended up finding a fix, replace the ckdisk (do I have the name right? I don't think so) with an empty text file to "fool" NT into doing nothing. How utterly advanced.

>Virtual memory should not slow down the machine.

Bullcrap. If you can find a hard drive that has 60ns access time, and costs less than the National Debt, I'll agree with you. Until then, VM can't be

as fast as real memory and therefor MUST slow down the computer - it's a
physical reality like gravity. FAST hard drives typically have 9 ms access
time - 1000 times slower, more-or-less, than RAM. And transfer rates are
typically on the order of 1 to 3 megabytes per second, versus RAM transfers
of 2000 megabytes per second on a 33 MHz memory bus.

VM slows down computers. QED. That's why our servers (in the
software lab here) typically run between 256 and 512 megabytes of RAM with
VM turned off.

BeOS certainly sounds to be a very nice Os but I've yet to use or even
see it in action, I am however VERY interested that you have seen BeOs
run on the same machine as TOS, what machine would this be?

What are you talking about? All virtually memory does is swap pages of
memory out to disk when you don't have enough real RAM, so what you
are saying about it not slowing the machine down unless you actually
use it is obviously true but you are stating the complete bloody
obvious.

Having the OS in ROM has little to do with disk swaps.

Many graphics cards I known of on the PC will work without a driver either. The reason is called the VESA video BIOS.

The VESA video BIOS is a standard for controlling the video mode and accessing the frame buffer + certain acceleration features (VESA2.0) on the PC.

DOS program (games) tend to use this because they have no other choice. OS/2 has a generic driver that can use it as well. I believe that Win'95 and maybe NT also have generic drivers that use the VESA interface. (I could be wrong.) Linux definately does. (Unaccelerated X-Server)

This is a total waste of the card's acceleration features however.

>To enable graphics acceleration, an extension would have to be loaded.
>A card will work, but it won't be all that fast until you use the
>extension (or control panel) to enable the graphics acceleration.

Aha. Driver.

>Perhaps it is very similar on PCs, but that's generally how it works on Macs.

A frame buffer (IE a card without acceleration features available) would get KILLED on the Windows market today.

Unless the card was very cheap, say $25, NO ONE would use it because it would be insanely slow compared to even cheap accelerated cards.

>useful on the screen.

A driver, by my definition (maybe not yours), is any piece of software that isn't part of the OS kernel, which communicates with a piece of hardware directly and presents an abstracted standard programming interface to the rest of the OS and/or user programs.

An extension which enables acceleration:
1. Is a piece of software that isn't part of the Mac OS Kernel.
2. Communicates with the hardware directly.
3. Enables acceleration by extending QuickDraw
   (a abstracted, standardized programming interface to the rest
   of the OS).

Therefore, I consider that this type of extension *is* a driver.

Yup... Just go to your local garage clone dealer and get a new drive mechanism. If the drive manuf. is different from your old one (such as epson) you might have to cut up your old case a bit however.

Just tell the garage clone dealer to make sure the drive is set up as drive a. At that point, you should just be able to plug it into the old connections in the 1040 and have it work.

The drive mech should be no more than 50 bux.

On a slightly different note...
Has anyone ever attempted to use a floppy tape
drive on any of the Atari's?

Typical MacVocate hypocrisy. It matters not that the process would be identical; ours still is but, yours is not.

Just plug in the card.
No further hardware configuration is required.
If Win is running the standard driver already,
no software configuration is required.
(the standard VGA driver IS the default btw)

They appear much the same and you've done nothing to differentiate them. Since it has been stated by that firewire developer that the core video standard is a dumb frame buffer, the two are quite

equivalent. Although VGA++ is a bit nicer than VGA, one is no more,
or less, plug & play than the other.

You just don't like that this makes your precious a bit less impressive.

(I'm still curious as to how well Diamond can foul up a Mac. <bfeg>)

3D Xpression+ vs. 3D Xclaim (ATI)

Why the distinction still? Can you show that this is not the norm?

>With PCI Macs, there is no special hardware needed to support Macs as
>long as the card conforms to the latest PCI spec.

So, where can I go to find a PC video board installed into a Mac?
I am primarily interested in the 3D Xpression+TV (in case you hadn't
noticed).

The same is true of PC cards. In Windows default state, you can
interchange any VGA card with any other VGA card without the
need for configuring hardware or software.

If you want to fully utilize the card, activate an 'extension'.

Both machines are identical in this respect.

>
>To enable graphics acceleration, an extension would have to be loaded.
>A card will work, but it won't be all that fast until you use the

extension, driver... both are extra software that the user must

have in place to enable the full potential of the hardware. Calling
a driver an extension wont make it any less of a driver.

>
>Perhaps it is very similar on PCs, but that's generally how it works on Macs.

Almost identical, actually.

Windows does not require an 'extension' to use a video card.
It is a standard delivered component of the OS. There is also
a version on the system ROM. The ROM is likely where the standard
Mac video driver resides.

>
>As such, the extension for a graphics card on the Mac is not so that a Mac

Then Windows has video 'extensions' as well.

hi,

I am in search of these games that you have in your closet, up in the attic or under the leg of an uneven table. Get some cash for those games that you don't play anymore. Sell them to me. If you have any of the titles below I will buy them. They have to be in working order of course and for the Atari ST. Thanks! Waiting to hear from you. Contact me at mykle@con2.com

Adams Family
Super Cauldron
Prince of Persia
Leander
Lemmings
Pirates
James Pond II
Fire and Ice
Underworld
Cadaver
Chaos Engine
Knightmare
Captive
Gods
Xenon & Xenon II

Software optimization techniques are universal. The biggest gains are
gotten by changing algorithms. The next biggest are by techniques like
tight assembly coding, loop unrolling, software pipelining, etc. These
are all OS-neutral.

> Maybe not good
>in practice, but how else can you explain the performance that most TOS
>applications display on even the modest of Ataris.

Such as?

I propose a simple test. JPEG decoding is a pretty well known CPU
intensive operation. Pick a JPEG image I can download and we'll both time
how long it takes to decode it. I'll use GraphicConverter, a well known
Mac shareware app. Just for good measure, I could run the same test using
xv under Linux / X, and maybe even under BeOS if I can find an image
viewer (I think they supply one with BeOS but I'm not sure). You can do
the same, and we'll compare results.

I don't even pretend that I think it's a fair test.

>As far as the Power PC blowing away the T060, you should really pick up
>the latest issue of Current Notes.

What's it got to say? As I recall, that's a print magazine, and it's not
exactly commonly available, so it's a bit much to ask me to just pick it
up. :)

>I can't speak for all T060 users and wantabees, but I see a hardware
>platform with much more potential and versatility than what is offered
>by Apple or Intel at a substantial lower overall cost. Just add a
>quality video card to an 8500 and you have far exceeded the cost of
>the T060.

The 8500 has quality video built in. The reason that video cards for Macs tend to be quite expensive is that there really isn't much of a market for low-end and midrange cards.

Last I heard, a T060 costs well over $2000. $2000 buys you 200+ MHz machines these days, either Wintel or Macintosh.

>Concerning legacy Atari software, the only problems I have with
>the availability of "new" applications is being able to afford

Just out of curiousity, what is that rate? I haven't followed Atari since I got out of it a few years ago. At that time the rate of new software development was really beginning to dive.

>Sorry Tim, my crystal ball says Apple won't be around that long without
>major reorganization.

Sorry Mike, my crystal ball says yours is wrong. :)

Not because I have incredible faith in Apple, though. I think they are on the brink of disaster. But if death comes to Apple, it will likely be a long and malingering death. Consider how long Atari lasted with essentially no sales except to fanatical followers (hell, I almost bought a Falcon, before I realized that a Quadra was more cost effective). Consider that Apple has a lot more market share than Atari ever had. Consider that they have over a billion dollars in the bank with which to absorb losses. (If nothing else, it would take a lot longer than a year to kill off that much money.)

The major reorganization already happened. It's now time to see what the results of that reorganization are.

> The real question will be if the clone
>manufactures
>are willing to invest in what Apple has purchased. This is of course my
>own opinion, but Apple's performance in the market does indicate
>problems
>on the horizon. Time will tell.

Problems on the horizon? They're hip deep in them now. The years of ineffective management of crucial development programs and abysmal marketing of the really cool technologies Apple has come up with have directly resulted in Apple's current woes.

If Apple's NeXT OS doesn't come out on schedule, they will be in a lot of trouble. The old Apple kept pushing Copland's release date farther back, but the new Apple cannot afford to delay "MacStep" (for lack of a better name) even once.

I am really disappointed. When I jumped ship to Apple, it looked like they were a very solid last bastion of non-Wintel computing. But they have since crumbled.

BTW, on a totally unrelated question: Have you ever used the Atari text editor Sudden View? If so, have you ever gotten it to work on MagiCMac? I wanted to play with it the other day, but although it appears to run, it refuses to recognize my password (SV requires password entry every time you run it). For some time I've been interested in trying to write something similar for the Mac, since SV is very cool, but I need it to play with so I can reacquaint myself with the details of how it works.

My PowerMac. OK, it's not precisely TOS, it's MagiCMac that runs on the same machine.

True. I perhaps cut too much of the context out of my quote.

> on the horizon. Time will tell.

Are you kidding? PowerComputing is on a roll. Power reportedly sold over 200,000 units in 1996. Not bad for a two year upstart. I bet that their revenues are at least $500 million. I would suspect that they will break a billion this year. And yes they are very profitable. Motorola shipped 40,000 units from late Nov-Dec period of last year. I suspect that they will do even better. Power is the next Dell/GateWay

Apple should make Claris public, a $250 million software firm. Just offer upto 50% of the company to the public and rake in the cash.

Claris, Power, Motorola and Umax could handle the OS as a consortium if something happens to Apple.

The Mac OS has evolved over nine years from System 1.0 to 7.6 with lots of the latest and greatest..

Next July will see Tempus and by Jan the first incarnation of Rhasopy with lots of good internet stuff.

> I'm sure "Sounds like you are defending.." is some sort of bait to be

Maybe so on your platform. Here in Mac land, $1599 buys an APS M-Power 603e200. 200mhz PPC 603e, 1.2GIG, 10X CD, 16 Megs/256K L2 cache and keyboard/mouse.

>
> You did what?

Did what?

Well, we demand better continously. I suppose you are satisfied with the status quo..

> Tempus? So what you are saying is that soon there will be good
> machines available but they won't be running the MacOS and these
> finally WILL be good, sounds about right. And Rhasopy is a very, very
> stupid name for an OS don't ya' think?

Tempus is System 7.7 and will be out in July. Tempus consists of the finished Copland components. Will have a native finder with multithreaded and the new 3d appearance manager..Thats my upgrade.

Rhasopy has some class and at first I did not know why they settled on that name until I found out the meaning.

Hi,

Is there a "find file" program similar to that on a Mac for the ST which
will search mounted volumes for the selected file, show you the path to
the file and/or allow you to run (access) the file from there.
Navigating and searching multiple mounted volumes get tedious.

According to the latest issue of Current Notes, the '060 equipped Atari
compares -very- favorably with (approx.) 150 mhz thru 200 mhz PowerPC's.

It's called GENGRADD. For an nonaccelerated driver, it seems to play Quicktime movies rather fast, and gets you resolutions like 1280x1024, depending on the card it detects.

>and maybe NT also have generic drivers that use the VESA interface. (I

Not. At least nothing like OS/2's GENGRADD.

More important for OS/2 are generic chipset drivers. This means, for instance, the same S3 driver works with all S3 chipsets and S3 chipset cards, without having to even reinstall if you install a new S3 based card. Ditto with Cirrus, Trident, ATI Mach 64, even the Matrox cards.

Wrong Darwin. I look at my Mac graphics card and the so called extension closely. The extension is far too small in terms of kb size to be a driver in the same sense in the PC drivers are. The Mac extension is more like a control utility, similar to all the utilities you find in PC cards as well---to enable, disable and set settings. The extension may only contains patches to the *real* driver, which I believe is actually in a ROM inside the Mac graphics card itself.

This is the only way I can explain why at the moment of installation without installing the extension, all the specific, and quite nonstandard video modes and virtual desktop modes of my card are automatically available and functional at the first bootup. Including accelerated features---I can remove the CDEV from my system folder and it still shows the effect of acceleration.

There are Mac drivers, but their nature is different from what we expect of PC drivers.

>

At least for my 1724PDS card, that extension isn't a driver. Again, it depends on the implementation---there is nothing stopping a vendor from implementing the driver as an extension, or as a ROM in the video card. The extensions of various Mac graphics cards are too small to be actually doing the work of a full driver. At best, they seem to be patches or used as a bridge between the OS and the real driver, which has to be on the ROM in the card itself. But then, part of MacOS is in ROM, so this is not surprising.

>Sounds a lot like Win95, actually.

No. It's just a utility, a switch. The real drivers are there
somewhere I believe in the graphics card itself.

In my case, I need the extension only to *disable* the acceleration and
to customize the key combinations to activate pan and zooming. In other
words, only to *change the default settings.* The card is functional
without the extension, including all modes plus virtual, pan and
zooming and acceleration.

In fact the settings are immedietely changed, including acceleration on
and off, as soon as the control panel extension is closed. I don't have
to reboot.

Looks more like a Timex 1000 or Sinclair ZX81. Ataris always had lower case characters.

>CAN I USE A DRIVE FROM ANY PLATFORM?

Besides the plastic front, Atari disk drives are standard Shugart bus ones (e.g. by Epson). If you find the same drive or one that is compatible with the front of your defective original, you might even avoid using a saw to replace yours.

F'up!

Thorsten

JEDI -
>   The same is true of PC cards. In Windows default state, you can
>   interchange any VGA card with any other VGA card without the
>   need for configuring hardware or software.

Except there are many cards that AREN'T VGA... there are the VESA
cards and the XGA, and many other TLA's that I don't remember and more
than a few proprietary ones... so you are saying that the PC's PnP
works often - and thats as good as the Macs always (or damn near it).

There is a difference in degrees - and you will be raised to a new
level of "assholishness" if you are so blind that you can't understand
the difference between Macs PnP and PC's russian roulette (usually it
works - but sometimes it blows your head off).

BZZT! WRONG! There are many cases where it does. Most cases it does
not.

It's not a fair test...

Let's go one step further.

Here are my results using ImageCopy on a T60 with 32 MB RAM.
800*600*256 screen resolution

20 640*480*24-bit JPEG images set up as slideshow.

* note: the processes involved here are, load from hard disk, decompress,
dither to 256 colours and display.

26 Seconds.

Caveat, ImageCopy only lets you choose "full" seconds as wait time between
images in a slideshow, ie: 1 second is the smallest wait time. If I could set
Imagecopy to reload after .25 seconds, I do not know if the total time to
complete the slideshow would be better, I assume it would.

I already know how fast a 9500 with GraphicConverter does this test and it
is nowhere close.

All the best,
Chris @ Computer Direct

Softwindows is NOT CPU-level compatabilty - it's a software emulator.

You just contradicted yourself here.

Although Linux is quite a bit more intellegent about it's VM,
you will still take a performance hit if you depend upon it too
much; Linux developers admit as much. On the less robust systems,
this situation is magnified.

Unless you are running a big-iron OS and a fast disk, this is indeed
the case. The other micro-OSes just aren't quite 'modern' enough yet.
Even the ones that are can't outrun physics...

So figure out a way to get me these images and I'll decompress them and time it.

Slideshows are not desirable for a real test. You can't tell what part of the time was spent processing and what part waiting.

What I think I may do is tile together a very large image (say, 3000x3000 resolution or so), in order to get a file that takes a long time to open, so it can be timed properly. We may also want to load things from a RAMdisk, in order to eliminate the variable of who happens to have the faster HD.

(Funny thing is, I just realized my challenge won't prove anything one way or the other... both sides will have things to fall back on, because it isn't exactly a rigorous test.)

Oh crap. They are streamlining the budgets of all divisions actually. It's like
the US Goverment---productivity and emphasis is not the reflection of budget size.
Efficient utilization of money is.

Fastest selling software of all time?   You mean, the fastest preloaded software
of all time. There are a lot of people dissatisfied with the product there.
Sure, they encounter things like not enough memory to run it as fast as they wish
it to be, or that it lacked the proper drivers, or proved to be too slow for their
systems, or took up too much space. Whatever the reasons are, they were sold with
the promise of the product and that promise didn't get fulfilled. I just have a
friend whose Win95 installation into her 486 notebook resulted in a dead
unreadable drive and a black screen.

IBM has one of the most vigourous, most extensive programs for Java anywhere else on Earth outside of Sun. In fact, Java is a prime strategic directive for all IBM divisions.

Rgds,

Chris

ZeDud Propaganda announces:
Villain H. Doors III of Monopoly$oft announces a new operating system direction.
This direction will take Shutters 95 and Shutters MT into a new object platform
codenamed Chernobyl. It shall incorporate the new Exploder v5 browser right
in the interface. "This is going to be a Blast," Vill claims.

That's strange. I have a Stealth 64 VRAM (the 3400XL V's precursor,
964 rather than 968, and I have a Trion64V+) and it works for me.
That's really odd. I'll have to look into that.

] and all color depths supported by the video card.
]

You do need a driver that knows how to program the video card to use a video card. This is true of Windows and it is true of the Mac OS. In most cases, the driver is on the card itself, so the user does not have to install the driver from a floppy. Either way, there is a driver specific to the video card. The Mac OS, just as Windows, needs a driver to be able to program the card.

] Contrast this with the PC. The PC requires a special driver to
] utilitize any resolution or color depth above standard VGA (which I

Wasn't too good for Lotus either. Oh yeah someone
rode off with a bunch of pocket money but in the end????

Ditto a co. that once was known as Rolm.

It was bad market strategy regards Lotus anyway. IBM never
tumbled to what was happening on the net. Remember PROFS??

"Sell" means that A gives B a product and B gives A money in exchange for it. Often B proceeds to then give the product to C in exchange for money.

A preload is a sale, Chris. Microsoft is shipping products to hardware vendors and the vendors are giving money to Microsoft. The vendors then include the product in a larger bundle, which they then sell to end users, in exchange for more money.

I don't understand this attitude that a preload is somehow not a sale and shouldn't be counted as a "real" copy of the product.

I thought users use the OS to run apps. I suppose that different on the TOS
platform.

>
> Price is all relative. perhaps this machine is worth more to a certain market
than a slower 1500.00 PowerMac is?

I suppose. Must to be the ones with deep pockets. I highly doubt will be a
sustainable.. Considering the PowerMac hardware platform doesn't sit stil. Soon
MP boxes in the same price range as what you sell plus running the Be OS, Tempus
and Rhasopy..

If I'm not mistaken, he needs to get the latest version of ICD's hard drive software or HD Driver.... either one supports arbitration on a Quantum Fireball drive and it is arbitration that is needed to recognize the drive.

>060 that is slow. Considering a Powermac 6400/180 can be had for $1199. Whats
>your excuse for the high price?

I don't know what applications he was talking about BUT one app that
does spring to mind which AFAIK is unmatched on ANY playform is Tempus
2, on my 8mhz 68000 it is the fastest text editor have ever seen, I've
not seen anything that can scroll at it's speed on a very fast
pentium, I'm sure that there is something that will run faster than it
but you will need a processor tens of times faster than a 68000 to do
it.

In fact, it accounted for 2.5 billion of MS's revenues last year.

I tried OS/2 2.1, and then Warp3 and they weren't bad. However, the software I wanted to use and needed wasn't available, and I gave up waiting for it. I went to Win95 and now WinNT 4.0 which I like a lot.

OS/2 probably is technically better, at least than Win95, but I feel they missed their chance to really get a chunk of the market when Win95 kept getting delayed. I don't know why IBM can't seem to market very well.

: Fastest selling software of all time?   You mean, the fastest preloaded software of all time. :There are a lot of people dissatisfied with the product there. Sure, they encounter things :like not enough memory to run it as fast as they wish it to be, or that it lacked the proper :drivers, or proved to be too slow for their systems, or took up too much space. Whatever :the reasons are, they were sold with the promise of the product and that promise didn't get :fulfilled. I just have a friend whose Win95 installation into her 486 notebook resulted in a :dead unreadable drive and a black screen.
I'll have to say that when I was trying OS/2, there were a lot of posts from people whose OS/2 installation resulted in a dead system as well. Any OS of any complexity is going to have installation problems on certain configurations. I never had any problems installing OS/2, 95 or NT. Just luck I guess.

I have a friend who is running Win95 on a 486/66 with 16M RAM, and they are satisfied with it. Go figure!

I agree with you Steven.

If I remember correctly, IBM tried selling their systems and notebooks with OS/2 preloaded, and they ended up switching to preloading Windows just like everybody else. I would assume, therefore, that preloading doesn't automatically result in success for the preloaded product.

I get some catalogues from companies that sell computer
systems, and they preload Lotus SmartSuite on them as part
of the package. Should these installations be removed from
the profit picture and the user base calculations? I have a
couple of clients that purchases these systems, and the
first thing they did was call me and have me remove
SmartSuite and install MS Office, which they purchased on
their own rather than use SmartSuite at no charge.

I will grant you that MS strategy of charging for each
system sold whether Windows was installed or not did remove
incentive for manufactures to offer other operating
systems. I know that Dell allowed you to specify Windows or
OS/2 for awhile when you ordered a system from them, but I
don't think that lasted very long.

Good point, I'd not accounded for Be's implementation. But since it's not P-n-P (my appologies to Be if I'm incorrect on this point) you end up doing exactly what "JEDI" is claiming you don't have to - load drivers by hand. In this case you'll need Be drivers in fact, and I'll bet their even more rare than Mac drivers.

Personally I've always felt that ISA on the Be was one of the more backward-looking features of the system. Is the availablility of slightly cheaper Ethernet cards and internal modems worth the extra complexity and confusion? I personlly don't believe so.

> The BeBox uses its ISA slots for a multi-I/O card and a sound card. You

Contrary to what JEDI is claiming.

> IMO it probably would have been impossible to economically put in an ISA
> bus on computers like these in the past; it's only done now because very

If the OS/2 newsgroups are dying its because everything in Warp works so well
and everything is so smooth that there isn't a lot to talk about.  Frankly, I
enjoy
reading about all the Microsoft product problems.  It reinforces the good feeling
associated with knowing I made the best choice with Warp 3 and now Warp 4.

                                                                  Roger

Spreading FUD about what? What have I spread that has been FUD?

All I said was *IF*. It is always comming back to an *IF* with the PC. If your PC has X, then you can do Y. There's always that *IF*.

Regardless, you still need a separate driver, it is now the VESA driver.

>I'd like you to name a current DOS-compatible card _without_ VESA.

>don't need an -extra- driver. Got it?

Oh...then why was it suggested that I get the correct drivers for my video card to allow me to switch resolutions / color depth? Windows 95 supplies built in drivers for the chipset built into my video card, why should I need these *extra* drivers when Windows 95 already has a supported driver? So, with that said, I guess that I still haven't got it.

If you say so. I don't consider something that I have to install to
be "built in". If you want to call it word play, fine...it's word
play.

Everything that I do works nicely under NTW 4.0, so I don't see any reason to backstep to Windows 95. I'm sure I can get along just fine with Windows 95, but I have no reason not to take advantage of the power NT offers over 95.

It's not that I'm unwilling, I don't have any need to. As I've said, this really isn't an issue for me. I can't recall the last time I had to change resolution / color depth on my machine. I set it to the desired resolution, and forget about it.

>>I realize that with the right drivers and the right extensions, that I

>
>Suffice to say you are one of the only ones I've heard of to have this
>sort of problem.

Am I? Earlier you told me that I should get OEMSR2 to clear up this problem. I would be quite honored if MS included this ability in the

OEMSR2 release just for me, but I'm certain the reality is that they
did not. Apparently others have the problem as well.

>In other words - big deal, HTTP it. I don't know why your machine
>doesn't work like all of the other machines around, including mine,
>which probably has a similar chip in it, but you -do- have a solution
>to your problem that's staring you in the face.

Why do you think that I have a problem? You, yourself told me to get
OEMSR2 to gain this additional functionality. Since it was included
with OEMSR2, I would imagine that I'm not the only one having
problems.

Also, as I've said in the past, it isn't a problem for me. I don't
change resolution very often (I can't recall the last time I did) to
bother finding a solution for something that doesn't affect me.

What I am saying is, that the Mac OS has this capability built in, and
has had it for quite sometime. With Windows 95, I have to download
the "correct" drivers from Diamond, or install an aftermarket product
or upgrade Windows 95 to OEMSR2 in order to get it.

Simply put, the Mac way is more elagent than the Windows 95 way.
That's all I'm saying.

I'll explain: JEDI is quite simply dead wrong. The Mac does not need a specially made card, and never did. He simply doesn't have a clue what he's talking about.

I would if this were a problem for me. But it's not. The only time I
can recall changing resolution / color depth was to test it out for
this discussion.

Just out of curiosity, what do -you- think that "power" is?

>Am I? Earlier you told me that I should get OEMSR2 to clear up this
>problem. I would be quite honored if MS included this ability in the
>OEMSR2 release just for me, but I'm certain the reality is that they
>did not. Apparently others have the problem as well.

In OEMSR2 they included the ability, with generic chipset-level drivers, to change color and resolution on the fly, whereas in R1 of Win95 they included only the ability to change resolution on the fly, and OEM manufacturers could then add features to the basic drivers. Any deviation from that norm is unusual.

>Why do you think that I have a problem? You, yourself told me to get
>OEMSR2 to gain this additional functionality. Since it was included
>with OEMSR2, I would imagine that I'm not the only one having

I also said a normal R1 owner of Win95 (release one, August 95) can switch resolutions without problems; I don't know why you have them.

>Also, as I've said in the past, it isn't a problem for me. I don't
>change resolution very often (I can't recall the last time I did) to
>bother finding a solution for something that doesn't affect me.

Then why are you posting about this? To make your Mac point. And

I've given you a fix, which I believe negates the Mac point - for the
most part.

>What I am saying is, that the Mac OS has this capability built in, and
>has had it for quite sometime. With Windows 95, I have to download
>the "correct" drivers from Diamond, or install an aftermarket product

You should be able to change resolution without any problems; I'm not
sure why you have a problem. That is odd.

>Simply put, the Mac way is more elagent than the Windows 95 way.
>That's all I'm saying.

Based only on your experience, you might have a point. Fortunately, I
don't think that's typical.

CPU level compatibility was promised. It was touted as one of the many
advantages of RISC technology. It never materialized and is now getting
swept under the rug.

Nevermind that Mac PC cards will most certainly cost you more than
an entire new PC.

Quite frankly, you aren't qualified to make that comment.
You don't even have any decent level user experience that
isn't greatly outdated. Furthermore, you've demonstrated
a complete computer illiteracy when it comes to technical
details of any kind.

Fill in the details, if you can.
Things that can be accomplished through applications
(like cyberstudio) don't count.

Furthermore, such 'distinctions' serve no purpose other than
'genetalia' waving.

It need not be modern. It needs to only do what is required of it and not place uneccesary barriers to that end.

Most of the features that are new and nifty these days are actually rather old. Most new microcomputer OS features are typically merely repeating what has been done on the larger systems in the previous DECADES.

>
>Of course it is. When was the last time you used it?

> but for TOS and Atari apps it is plenty fast.

Modern microcomputer OSes have a nasty tendency of 'getting in the way' in that they eat up a large chunk of the machine they are running on.

The genius of TOS/GEM was that it delivered quite a bit while not bogging the machine down. It is appropriate for a 68000/8. System 6.0 was not and it showed. In a similar fashion, OSes have continued to grow faster than the hardware.

Until the recent drop in RAM prices, most 'modern' microcomputer OSes were painful to use as they would not fit inside the machines they were designed to run on. Innapropriate tactics, designed for highly concurrent, mult-user, high IO bandwidth machines were used. This virtual memory would slow down a Mac or PC to the point where an ST and it's 'primitive' OS could catch up.

ROM was faster than floppy in 1986.
ROM is faster than HD now.

Only a recent memory glut has saved the current crop of 'modern' machines and their OSes from running at the speed of a hard disk (50 times slower than a 68000/8) rather than their full potential.

Try to use one of these modern OSes in twice the memory capacity of an ST and see what happens. Then run the austere yet relatively perky ST next to that 'modern' machine.

I remember an even more recent fiasco by IBM. When Win95 first came out, IBM, unlike all the other major PC vendors, had decided to believe in its own "White Paper" lies that Win3.1/DOS was actually "better" and that Win95 wouldn't sell and no one would want it, etc.

When 1995's fourth quarter selling season began, IBM had, because of that folly, a bunch of Aptivas in the channel pre-loaded with Win3.1/DOS that weren't selling at all; everyone was buying new PCs for

Christmas 1995 with Win95. (so much for the dumb uninformed 'sheep' masses that the OS/2 advocates here like so often to refer to).

The end result was that IBM scrambled like mad, according to a Radio Shack executive friend of mine, shipping "Free coupons for Windows 95" to go with every Win3.1/DOS pre-loaded Aptiva, still sitting on shelves and in warehouses.

He told me that he got cases of them to distribute to Radio Shack stores just before Christmas, but that nevertheless, IBM lost a bunch of sales as a result, since the consumer obviously preferred Win95 pre-installed.

According to him, this was the cause for much of the major recent 'bad blood' that ensued between the PC Co. and the OS/2 PSP crowd, which had convinced the PC Co. albeit briefly, that "Win3.1/DOS was better" and that the consumer would reject Windows 95.

IF is something very few people have to worry about, hence FUD.

>>If you don't know, then why are you spreading FUD?

>Spreading FUD about what? What have I spread that has been FUD?
>All I said was *IF*. It is always comming back to an *IF* with the
>PC. If your PC has X, then you can do Y. There's always that *IF*.

Kinda like *IF* the Mac has 32-bit addressing (aka death-knell for
certain 030-Macs that now can't run System 7.6, eh?) and *IF* the Mac
has color. Kinda silly nowadays.

>Regardless, you still need a separate driver, it is now the VESA
>driver.

It isn't a seperate driver - it's in the BIOS of cards.

>>I'd like you to name a current DOS-compatible card _without_ VESA.

>But you still need a driver, you need the VESA driver...or am I wrong?

Every OS in existance needs a driver at some level. Or were you
disputing *that* point? That would make for a short debate.

>>Let me say that again - with Win95 if you have a supported chipset you
>>don't need an -extra- driver. Got it?

>Oh...then why was it suggested that I get the correct drivers for my

>95 supplies built in drivers for the chipset built into my video card,
>why should I need these *extra* drivers when Windows 95 already has a
>supported driver? So, with that said, I guess that I still haven't
>got it.

Some drivers offer extra functionality, as with any OS. The things
we're now discussing are generic to any OS.

>>...as does the PC for VESA modes and for any chipset built into Win95.

>You need the special VESA driver do you not?

This is why you're spreading FUD - you don't know, and then you state,
as if it's fact, that you do need oodles of special drivers. Sigh.

Let me say it again - in the BIOS of cards today, there exists VESA
drivers. In the Win95 OS there exists drivers for many cards found on
the market today. It's that simple. And - also - every OS requires
drivers. Everything. At some level, there's a driver involved.

>>The standard in DOS is VESA, which, as we've been over, is on modern
>>cards.

>But still requires the use of the VESA driver.

You keep repeating that. Every OS requires drivers.

>If you say so. I don't consider something that I have to install to
>be "built in". If you want to call it word play, fine...it's word
>play.

You don't need to install VESA drivers for most cards, and you don't
need to install Win95 for most PCs you buy - although you certainly
can reinstall it, as you can reinstall MacOS, if you wish.

This is going in circles. Both OSs, as with any OS, require drivers.
At some level, they're there.

CPU level compatability with the x86 was never promised by any member of the main trio which worked on PowerPC (Apple, IBM, Motorola). Apple promised some degree of 68K compatability through software emulation.

There were plenty of rumors for awhile about a IBM project, the PowerPC 615. It was to be a 2-in-1 CPU combining x86 and PowerPC. You cannot call it a promise since IBM never announced it, denied most if not all of the rumors and leaks about it, and finally announced (at least a year ago) that the project had existed but was canned due to technical problems.

>   Nevermind that Mac PC cards will most certainly cost you more than
>   an entire new PC.

I agree that this is the case. However, from my perspective as an engineer, I can easily see why. They will never sell nearly as many of those boards as a single PC motherboard manufacturer will of its motherboard design, so the board cost is higher (volume production really cuts costs a lot). And the system ASIC they have on it to glue everything together is produced in even less volume relative to ordinary PC chipsets, since PC chipsets are typically sold to many motherboard companies.

If you are in the market for a PC card, you must basically decide whether the bad pricing (equivalent to buying an entire PC with the same specs) is worth the advantages (you can use the same keyboard, monitor, mouse, and no desk space is taken up by a second machine).

As usual, you failed to think at all.

Your advocacy issues are not welcome outside the advocacy groups (probably not real welcome there, either, but that's another story).

I tried asking you to contribute positively - we Atari users have more in common with most Mac users than with Windows users; but you can't seem to distiguish between your opinions and the laws of nature, so your posts are little more than rants, with no factual basis. Get lost.

Ever seen BeOS? All sorts of modern features. Faster interface response than TOS, on the same machine. (I can crank up ten or so instances of a little 3D rendering demo, causing the CPU usage to peg at 100%, and BeOS will still maintain instantaneous response to mouse clicks and keyboard events for the foreground app.)

Uh, yeah. Whatever. VM doesn't cause a performance hit unless you use enough memory to force it to start swapping pages out to disk. In other words, it lets you use your computer for more things if you want to. This has nothing to do with whether an OS is designed to run a huge multi-user behemoth or your personal computer (indeed, if you want a large compute server to have decent performance, you must put enough RAM in it so that it doesn't have to swap often, or else users will complain that the machine is a slug).

> ROM was faster than floppy in 1986.

> ROM is faster than HD now.

So what's your point? That we should stay mired in the backwaters of computing just to be absolutely guaranteed that a disk swap operation will never happen?

The absurdity of this position is astounding. If it were true then would
not these very same ISV's see MS (makers of Excel, Windword, et al) as
heavy competition??

Oh? Describe is in trouble for its mismanagment, Smartsuite/2 only came out with half OS/2 native and none of the previous Lotus products are on the level to compete with other OS/2 products. IBM's own DB2, long ported to OS/2 before Lotus was in IBM's eye, and even more strategic to IBM than Notes with much more backing behind it, never stopped OS/2 from getting a lot of database products as well, such as Oracle. Tell me how Notes competes against Galactic Civilizations and Deskman/2 for instance.

Sure, and I bet you will count every show in cable TV as a "sale"
whether you want it, watched it or not.

I bet every tax filing to the US goverment is a "sale" to you too.

Rgds,

Chris

Their drivers offer more than resolution/color changes.  It gives you
better performance as well as "virutal" desktop--at least when you
install their OnControl utility (which is part of their driver
distribution).  The OnControl will allow you to change desktop size
along with resolution on the fly.  It also adds the Start menu to the
left button clicked on any open desktop space--kind like what X does.

It's worth the 1.2MB bandwidth it takes up (this is the version for my
wife's 3200 XL card--yours may be larger/smaller).

You must be joking! I was reading a Win95 newsgroup a few weeks ago,
and some Teamster popped in and said something like, "You people are
having so many problems. If you want a problem-free OS, try OS/2
Warp!". Just out of curiousity (and having had many problems with OS/2
Warp in the past), I subscribed to an OS/2 *.setup newsgroup, and it had
all kinds of big problems being grieved. "Blue screens of death in
Merlin" was a big thread, people were complaining about frequent traps,
freezes, how much slower Merlin was than Warp 3.0, hardware
incompatibilities, etc. As a matter of fact, considering the ratio of
people using Win95 vs those using Warp, it seemed rather apparent that
there were probably more problems per user in OS/2 than in Win95.

This is a very good point. One that I wish the frequent Mac advocates here would consider before bashing the cost of a Direct T060. The limited production of these machines is the driving force of the "touted" high price tag. Even then, "major apps" aside, the Direct T060 (Hades) is at a performance advantage over even the fastest of Mac's because of the TOS operating system utilized. For most users of the 060 clones, this is the driving factor behind their purchase, major apps aside. The Atari user that requires features such as built in ethernet has probably already purchased a Mac as it has been a standard feature for quite a few years. For the home Atari user, the ability to utilize a DTE rate of 230kb has been available for quite a few years. The talk of Apple adopting a major alternate O/S has been going around for quite some time. Maybe it will happen. There are several alternate O/S's for TOS based users to choose from. Many already have supporting applications that are readily available for download, generally freeware or at a modest price. No need to see what the Be O/S might offer the PPC user. One thing is for sure, you probably won't be upgrading a Claris or Adobe product for a Be O/S replacement app. Most TOS apps function equally well under any of the available O/S's, something TOS users have under stood for quite some time. The T060 is a new beginning for the TOS platform. The expensive proprosition of upgrading a Falcon to a 040 CPU becomes an inviting alternative when what you stated above is taken into consideration concerning limited production and pricing.

Yep, but for now all you have are demos. You don't mention what machine
your
are running the Be O/S on. Same machine? Are you saying that there is a
port
of the Be O/S for TOS based machines? If you are refering to a Be Box,
then
why wouldn't the second CPU be available while the other is pegged at
"100%".
I would hope that this is what the machine was designed for. My god,
could you
image a dual processor T060 running two copies of MagiC at the same time
in
two different windows on the same 21" screen. It boggles the mind.

>
> Uh, yeah. Whatever. VM doesn't cause a performance hit unless you use

Then why in Steve's name does EVERY form of video capture software

require
or recommend that you turn off VM for best performance? It's because the
Mac
O/S is always watching:).

How can you consider ROM based operating systems to be " mired in the
backwaters
of computing"? You sound smarter than that. Almost all embedded systems
used in
industry utilize a ROM based operating systems. It is more efficient.
When was
the last time you had to boot your 5 axis CNC mill from floppy or hard
disk?

Mike

Bwagh haa haa haa. Peter, you really are a dork. You are comparing TOS 1.0 from 9 years ago to the likes of TOS 4.04, MagiC 5 and Geneva which are operating systems used on Ataris today. Why, going on that i can say that MACOS doesn't have any colour at all and still uses small 12 inch screens... why, I might even go as far as saying that PCs use something called MS-DOS 3.xx and no window environment.. hey... I can even say that Unix doesn't have a woindowed environment!

GET REAL Peter!!!

I would have to disagree. The driving factor is that people who buy one must really have an attachment to legacy Atari software that needs to run as fast as possible. Sure, TOS responds (relatively) quickly, but the OS only does so much. When it comes down to how fast your computer does compute-intensive tasks, a PowerPC is going to blow away the 060.

>The talk of Apple adopting a major alternate O/S has been

Haven't you heard? Apple bought out NeXT. The NeXT generation Mac OS will be NeXTStep. (Sorry, couldn't resist the obvious pun.) They plan to keep releasing System 7.x updates for a couple years, but the new OS based on NeXTStep will be the flagship OS. Apparently they plan to release the first version in about 1 year, which is actually realistic since it's a complete OS already and they've got the entire NeXT development team.

You should see Tempus scroll on a T60, that is I mean, you should try and see Tempus scroll!

The Apps I refer to are Calamus SL96, DA's Layout TC v6, Photoline,
DA's Repro, faster than comparable feature wise Mac or Win apps.

The T60 is quite likely the fastest "System" on the block.

I say "System" because there is little doubt that there is faster
hardware, but that hardware is bottlenecked by inefficient programming.

All the best,
Chris @ Computer Direct

I have to disagree with you here, only because we sell the machine
and have sold it as well DTP software to major pre-press houses.

The T60 with Calamus SL or DA's Layout outperforms any PPC or Pentium
in it's price range.

You would really have to experience it to understand it. Words cannot
describe the performance levels attainable.

>Haven't you heard? Apple bought out NeXT. The NeXT generation Mac OS
>will be NeXTStep. (Sorry, couldn't resist the obvious pun.) They plan

This is probably the best news for Mac owners, but it is much further
than 1 year away... Sometime in 1998 is the ETA and as we all know from
experience, this may likely be delayed. By then I believe MS WinNT will
have made such a dent into the pre-press market that NexT/Mac OS may
be too late.

I sincerly hope that this does not happen though.

I don't know if I'd call it a new beginning, but it's certainly a major leap
forward in the evolutionary process. PCI expansion slots, a fast processor

with full "real" MMU, and TOS for people who don't want to bother with
disk-based OSes.

If you haven't yet reached that point then you aren't really using
the virtual memory now, ARE YOU? You could just as easily turn the
toy off. However, if you were to actually actively use any non-trivial
amount of VM, Mac's and PC's are crippled.

Virtual memory was developed in one context and then applied to another.
This is a simple matter of computing history and architecture for those
who know and understand the issues involved.

>words, it lets you use your computer for more things if you want to. This
>has nothing to do with whether an OS is designed to run a huge multi-user
>behemoth or your personal computer (indeed, if you want a large compute

Actually, it does. The disk and the bus it is attached to has to
be up to the challenge. Otherwise, your machine takes a HUGE performance
hit should it ever decide to use that nifty virtual memory. This is
quite easy to demonstrate with a microcomputer.

>server to have decent performance, you must put enough RAM in it so that

>computing just to be absolutely guaranteed that a disk swap operation will
>never happen?

So? How is TOS a backwater? One has yet to address that. All you
MacVocates can come up with are application level toys.

However, since Petey-Boy himself seems to think that the OS is just
a pathway to the apps, then great OS sophistication really isn't
required. There is little that MacOS or Win95 has that cannot be
grafted upon TOS at the applications level. Most of what they have
are bells and whistles.

Software should be designed to run on the hardware of today, no 4
years in the future. While petty justifications for braggadocio are
nice and all, computers are tools in the end. They either do the task

you desire in a satisfactory fashion, or they do not. Beyond childish
rhetoric, you have said nothing. How does TOS limit the user? Which
of these limits is not addressed by MagiC 4.0?

It might not be all that complicated, but that is still not plug and play.

Actually, I was refering to being limited on the Mac. I have never seen a
Mac with all its expansion slots filled (well, except those that were
pizzabox style Macs).

> >My roommate has a PC that has one PCI slot left. He has added nothing to

He has a total of 3PCI and 3ISA (one is a shared PCI/ISA slot that makes
for 5 slots if I have his configuration right).

Taking up two of his PCI slots, he has a graphics card and a SCSI card. This
was how the machine was shipped.

Taking up two of his ISA slots, he has a sound card and a modem card. This
is how the machine was shipped.

He has one free PCI/ISA slot that (according to him) can be used either as
a PCI slot or an ISA slot, but not both at the same time... though perhaps I
misunderstood him or perhaps he is mistaken.

In any event he has little expansion left whereas Macs come with at least 3 PCI slots free. Things like SCSI(and/or EIDE), graphics and sound are on the motherboard and don't take up any slots.

Yes, but the 'investment' in the original card and monitor is not lost on the Mac. The old card and the old monitor will work just fine with the new ones so you aren't forced to sell anything or thow anything away (unless of course you want to... you have the choice).

Maybe you keep the old monitor (as long as you purchase the appropriate card to use both the new and old monitors), but the other graphics card is either going to be scrap or it will be sold at a price much lower than its initial cost with a PC.

Huh? I still don't see why the choices made by the Intel based PC
industry and its OS makers can be made to be virtuous because it was
really hard to impliment (and not implimented terribly well at that).

It certainly may have been an amazing feat, but I doubt it was healthy
for the industry. It is certainly not something for the PC industry or
its advocates to brag over.

"We made some terrible choices a short while back, but we stuck with them
and through a lot of pain and effort at your cost, managed to get it all to
work... sort of. Isn't that great?"
-The PC Industry

Apple's 'feat' may not have taken nearly so much effort, but it was
certainly a better choice. To praise PCs for having people go through
more effort for worse results is silly.

Thus we can reasonably assume you consider the various kludges from Redmond
to be "backwards?" One of the iggest causes of GPFs (or whatever Win95
calls it now) has always been memory "protection" that didn't.

Ah, all of a sudden Apple is responsible for making something they didn't
design easy to use. Since ISA is brain-damaged past the point of repair,
your little challenge is absurd.

However, comparisons weren't being made between memory architectures. Comparions weren't being made between entire whole systems either.

Comparisons were being drawn between two cpu families ONLY.

In that context, isolating the effects of the memory subsystem upon relative performance is quite appropriate.

Uber-tests are really quite limited in an enviroment where you can customize and fine tune nearly every part of the system. If a particular system is an underperformer it is really quite difficult to determine WHY that system was an underperformer. The benchmark will tell you to avoid buying that particular machine but little else.

Hardware elements have to fine tuned in order to isolate (as much as possible) that which we want to derive information about.

One of my original assertions was that memory architecture was probably more responsible for relative performance differences between PC's and Macs than CPU speed in benchmarks that show a statistically significant difference between the two.

I'm not dense. I just realize the implications of 'No drivers'.
Even the more technically literate MacVocates admit that 'No
drivers' severely limits the usefullness of mac video hardware.

>monitors as you have PCI slots. On some machines this is
>as high as six! No drivers, no drivers, no drivers. Get it?

It's a nice parlour trick. However, the restrictions imposed
by it would not impress any PC user. Dumb frame buffer cards
are ancient history for us and very substandard. This is
what you have to turn your overpriced mac video cards into
to achieve 'No drivers'.

This is rather pathetic considering the ~$1200/$3000 one would need
to spent (or have spent) on video cards/monitors.

ironic meaning to that initial Mac commercial...

Enjoying your life in Oceana?

>'drivers' out of your PC and see if you get any video. You won't!
>I can ALL of the extensions out of my system and I will still get
>video!

Actually, you rube, you can remove all of the drivers and still
have video on a PC. This is known as VGA.

That is why I have been refering to Mac PnP as VGA++ you poor delluded
fool. Had you been paying the slightest bit of attention, weren't
blinded by your own advocacy or had any technical understanding, you
would have seen that.

IBM PC video cards have always been PnP in that respect. Much like their
newer Mac counterparts, they depend upon a driver burnt into the system
ROM in order to function. VGA++, CGA85, TurboHercules...

Here is one thing I learned about PC cards. It's the cards that support Mac like features---gamma correction, multimonitor support, pan and zooming, virtual desktops---that are also making Mac cards.

Here's another thing. If I use install DirectX into a Windows 95 system, which is often installed by a game, all that fancy stuff above and my Matrox utilities under Windows 95, just went to smoke. I mean, literally removed by the DirectX video driver. Most annoying. You have to reinstall the original drivers to get them back. Annoying, if not subject you to unnecessary risk. Which is why I don't install DirectX anymore in my Windows 95 systems, and they're all happy as a pod for this. It's great to use pan and zooming to watch movies for example, and a virtual desktop is great when you have lots of things open in your desktop, (especially when you are in the internet and doing a lot of stuff simultaneously) things I am also using in my Mac with a graphics card.

But the nice thing about the Mac is that I can still play hardware accelerated games while still keeping all these features.

Rgds,

Chris

Give me a condition, under Win95, under which I need to reboot to change screen resolution. (That's what I referred to in "No it doesn't" above.) Then give me a situation, under Win95 SR2, in which I need to reboot to change either resolution or bitdepth.

I await your reply, Tom.

Dear Atari Fans. I have a problem. My friend in Turkey has a professional musik studio. He has an external 540MB harddisk, but he needs more hd space to record audio. He has bought a Hd. Quantum Fireball 3.2gb. But Atari

Falcon 030 doesn't seem to recognise the HD. What can he do. Is there a program that helps to solve this problem. Thank you for your time...

None of which have stood to any sort of scrutiny though. Mac cards can support hardware pan and zoom. They can support acceleration. They can support all the other features. In addition they can use drivers in the OS, on disk, or on the card itself. The Mac has done this since the

1980's, when the Mac II came out. They do this in all software. They have a single API. The card can tell the OS that it's accelerating certain things and not others, without changing the driver at all. You can run accelerated on one card, partially accelerated on another, and dumb on a third all at the same time. You can plug in an accelerating video card (or simply and accelerator with no video out) and have it drive all the other card, dumb or smart.

The same is simply not true for the PC world, even today. You simply don't know anything about how QD works, and that's becoming increasingly clear.

> It's a nice parlour trick. However, the restrictions imposed

> are ancient history for us and very substandard. This is
> what you have to turn your overpriced mac video cards into
> to achieve 'No drivers'.

The multiple monitor support works fine on any card, accelerated or not. You simply don't have any idea what you're talking about.

> This is rather pathetic considering the ~$1200/$3000 one would need
> to spent (or have spent) on video cards/monitors.

The ATI card costs the same as the PC version. In fact, I've seen it (here in Toronto, ATI's home) for LESS than the PC version. Macs can use all the same monitors as PC's. Once again it's clear that you don't know what you're talking about. I don't know what the psychological afflicition is that forces you to keep talking like this, but every word you post makes you look more the fool.

> Actually, you rube

Now name calling. I suppose it was inevitable.

After you install DirectX, reinstall your old drivers.

If your old drivers include DirectDraw support, then DirectX will work
just the same.

You *can* have the best of both worlds. :)

Here's what I found:

Using the standard S3 video driver supplied with Windows 95, when I went to resize from 1024 x 768 to 800 x 600, it resized the desktop to 640x480! It asked if I wanted to keep the new settings, to which I responded no! When I went to change bit depth from 256 colors to 64K, it asked me to restart windows.

The reality of practice would appear to contradict you 'Bright Eyes'. Given that for 16 years, a wide range of PC motherboards have managed to interoperate with a wide range of ISA expansion cards, your comment is quite absurd given the available observations. When one considers that this 'non-standard' has also been used by Atari ST's and Amigas' with the same level of success: you are the moron.

ISA cards don't care what machines they are running on. A relatively sophisticated de juere standard is apparently not required for them to do so...

Don't tell it to the Atarians or the Amigans. However, they aren't the types to let themselves be stopped by a 'barrier' or two.

It's all just current running accross some wires after all.

If the software can adapt to the hardware, you do need too.
The Mac seems to be the sole platform unwilling to do this.

Name one that is not.

I have an old 256k PGA card that is as plug & play as any Mac video
card. I'd just need to tell the OS to expect a change.

>
>> Most of the problems

```

     Reserved IRQs and BaseAddresses.
     In a similar fashion, multi-IO cards are just as plug & play
     as are most (8/16) soundcards.

     The hardware is a bit overspecified however, the interface to the
     OS is not.

      If you wish to limit your hardware choices that's your perogotive.
      However a PC user need not be so limited. Furthermore, a PC user
      can impose such limits upon him or herself and obtain a level
      of plug & play quite similar to that found on the Mac and yet still
      have more options to choose from (than a Mac user).

      I can just imagine what Diamond could to Mac Clone & Pray...

It's ABSOLUTELY the same as Alpha and PC, you need to have a Alpha driver, and an Intel driver, yes, even though both will run under the same OS. Do you know ANYTHING about this stuff?

Maury

Did it happen once? Every time? That's certainly unusual - I'll
grant you that.

>responded no! When I went to change bit depth from 256 colors to 64K,
>it asked me to restart windows.

That's normal - and I even said that above - because you're not
running OEMSR2 of Win95, nor are you running QuickRes. As an easy and
quick fix, grab QuickRes (it's perhaps 20k or 50k) and run it at
startup. It goes into your little bar at the lower right of your
screen and handles resolution changes flawlessly.

>   with the same level of success: you are the moron.

I repeat: there is no standard. Despite cards sort-of working all these years, there has never been a centrally defined standard (in the engineering sense) for the ISA bus. For 16 years, motherboard have been able to interoperate with a wide variety of ISA cards, and the cards with each other, in a hit-or-miss fashion. Probably the only reason that most things work with one another is that ISA is very simple and (usually) operates at a fairly low speed.

As far as use on other computers goes: I know with absolute certainty that ISA was never available on the ST. The only expansion buses used by Atari were various proprietary processor-direct designs and VME (which is an example of a standardized bus, BTW).

I am nearly certain that on the Amiga, the use of ISA was limited to "bridgeboards". The ISA backplane in several Amiga models wasn't connected to anything on the rest of the motherboard. It held ISA cards which interfaced to a PC-on-a-card, the so-called BridgeBoard which sat in the one slot which had a Zorro (Amiga expansion bus) connector collinear with an ISA connector. The Amiga itself could not use ISA cards at all.

There is a much better example for your side of the argument out there. Do you know what it is? I do. (But it's not a very strong example, since very few ISA cards will work in the machine in question...)

>   ISA cards don't care what machines they are running on. A relatively
>   sophisticated de juere standard is apparently not required for them
>   to do so...

As I demonstrated above, ISA cards basically run on one architecture. You are simply talking through your hat, as usual.

>   Don't tell it to the Atarians or the Amigans. However, they aren't

```
>    the types to let themselves be stopped by a 'barrier' or two.
>
>    It's all just current running accross some wires after all.

Sure, but if you want to do anything more than programmed I/O with no
interrupts across ISA (i.e. very slow), you MUST have a good deal of the
support hardware present only in a PC.  If the machine is not a PC, it has
to emulate that hardware.

>>What people have been trying to pound into your head is that OF lets you

>
>      If the software can adapt to the hardware, you do need too.
                                                        ^       ^
I am assuming that there should be a "not" under the first ^ and one less
"o" under the second, otherwise this sentence does not make sense.

You do not need to?  Well, I suppose if you don't want to have automatic
configuration so as to avoid bugging the user by forcing him or her to set
jumpers and allocate IRQs and so forth, you don't need it.  Frankly, I'll
take the other option.  I'll take a method that lets radically different
machines use the same cards and automatically configure them.

>      The Mac seems to be the sole platform unwilling to do this.

What a load of BS.  You've been told repeatedly about the exact advantages
of the Mac driver model as opposed to the PC, but you are still trying to
blather about Macs not having any drivers at all.  (Which was false.)

All right buddy, what KIND of video? Do you get 24 bits without drivers? Do you get support for ANY resolution on any size screen without drivers? Tell me about it! No, I'll tell you. You get 640 x 480 PERIOD. You get 256 colors PERIOD. because PCs require specific monitor card drivers to do anything else. Mac's system support for video may just be a dumb frame buffer, but unlike the PC, its a capable frame buffer. BTW, what does this 'Newer Mac Counterparts' crap mean. Macs had this capability when most PCs were still using DOS, Hercules mono, and 640 X 480 green-screen monitors. In other words, for a simpleton like yourself, Macs had it FIRST.

A Diamond Multimedia PCI card. I'd give you the exact model, but I
don't feel like restarting the computer to find out.

A couple of times...that's all I tried it. It is weird, but I've
grown to accept this kind of behavior from PCs. I'd look into it
further, but I don't use Windows 95.

>>responded no! When I went to change bit depth from 256 colors to 64K,

Another funny thing...as I mentioned above, it asked if I wanted to keep the resolution change, to which I had answered no. When I restarted the machine, it was at the new resolution. Also, when changing it back to 1024 x 768, Windows 95 told me that it needed to be restarted.

As for OEMSR2 and QuickRes, I realize they solve these problems but they are (using mac speak) extensions to the OS. I don't see any reason why this functionaliy couldn't be built into Windows 95 in the first place. Either way, I don't change resolution / bit depth frequently enough (almost never) to make this a very big inconvience for me. But it is one of the many little things that combined together, make the mac the machine for me.

The BeBox supports ISA. Same for PPCP and PREP (these are PowerPC
common-platform designs). These platforms use a PCI<->ISA bus bridge
chip, a fairly common part.

The BeBox uses its ISA slots for a multi-I/O card and a sound card. You
cannot use just any sound card or I/O card, as they support only a few
models.

IMO it probably would have been impossible to economically put in an ISA
bus on computers like these in the past; it's only done now because very
cheap PCI<>ISA bus bridge chips are available. Designers don't have to
spend a lot of money on custom hardware to emulate PC interrupts and DMA.
It's cheap enough that it doesn't matter that you can't support many
cards.

With VESA you don't need a driver (a software driver) to take
advantage of higher resolutions.

With Win95 if you have a supported chipset you don't need an extra
driver.

In all cases _something_ tells your hardware what to do, but it's in
the ROM BIOS or the core of the OS.

As a former Atarian, I can say with no hesitation that no ST ever supported ISA cards, nor could they have if they wanted to.

> > It's all just current running accross some wires after all.

For all intents and purposes the ISA "bus" is a backplane with the 8080's pins on it, much like the S-100 bus it followed. If you don't have Intel IRQ's and such, it just don't work.

Yup, and I can't think of any that did (although you hint to ove above?).

Yup. Since ISA only supports Intel-ish chips and support hardware, that's somehow an advantage.

It sounds like you might have messed up in your use of the slider controls a little bit.

>As for OEMSR2 and QuickRes, I realize they solve these problems but

OEMSR2 isn't an extension - it's Win95.

>reason why this functionaliy couldn't be built into Windows 95 in the

You need to use the right drivers - changing colors w/Diamond's tools don't require a reboot. In any case, QRes solves the problem. Why you don't want to try it is a mystery to me. Does your Mac use *no* non-Apple extensions?

If you need a 486 card, Orange Micro has them advertised in MacUser, MacWorld and MacWeek.

>

Are you stating that Powermacs do not have the capability to run Wintel 3 and 95? If you state that, you are dead wrong.. Apple, Relys and Orange Micro have Pentium cards. There is also SoftWindows..

The Be OS will contiunue to be developed for the PowerMac.   PowerComputing will ship a copy of the Be OS with all their units leaving the factory. At least 12 apps were shown at macWorld. Will see how it plays out. The Be OS is new, moderm and has no legacy to deal with. Hopefuly with a decent web browser soon, should put the Wintel/Mac to shame.

So what does this do to the Amiga? HP licensed some of C='s technology just
before they went under. About three years ago. C= at the time decided not to
go with PPC and instead use a HP risc processor.

What are those apps?  I made a mistake with pricing.  But $2700 is a lot for an
060 that is slow.  Considering a Powermac 6400/180 can be had for $1199.  Whats
your excuse for the high price?

I have owned a number of Macs, and a good number of PC graphics cards for my PCs throughout the years, but never installed a graphics card in my Mac before because they had always seemed costly. Until now.

Not only did the Monitors object recognize 24 bit color outright without installing anything, I get resolutions, real and virtual, all the way to 4088x1536.

Rgds,

Chris

ZeDud Propaganda announces:
Villain H. Doors III of Monopoly$oft announces a new operating system direction.
This direction will take Shutters 95 and Shutters MT into a new object platform
codenamed Chernobyl. It shall incorporate the new Exploder v5 browser right
in the interface. "This is going to be a Blast," Vill claims.

Here's the picture I have of Open Firmware:

It uses a version of the programming language Forth (*not* Fortran), an interpreter for which resides in the boot ROM of every computer that uses OF. This is, of course, processor-dependent, but OF Forth is compiled into processor-independent p-code that is what is interpreted by this interpreter.

A device that understands OF would have some ROM with a driver written in OF Forth; this will make the device usable in any environment that has OF, regardless of processor type or whatever.

Thus, an OF multibooter would be capable of presenting a choice of boot disks on one's screen and could interpret some keyboard/mouse actions as making a selection.

Is that a fair picture?

Not as far as I know, unless I have a secret life where they whisk me off
every night and reprogram my brain so I have a different identity for 10
hours.  Is my name similar to the 'Computer Insider' guy's name, or was it
just random synaptic firing that prompted you to ask?  :)

```

Yep. You could easily write a multiboot program for OF.

```

>Possibly, but three different times...I doubt it.

Try Diamond's utilities and see what happens, then. I have a S64-DRAM (2001-Video, Trio64V+) and Win95, both Aug95 and OEMSR2, work flawlessly with the built in drivers, although the Diamond drivers are nicer with the Aug95 release.

>>>As for OEMSR2 and QuickRes, I realize they solve these problems but
>>>they are (using mac speak) extensions to the OS. I don't see any
>>
>>OEMSR2 isn't an extension - it's Win95.

>You'll have to excuse my ignorance...I'm unclear as to what OEMSR2 is.
>I can't find a refernce to it on MS's home page. Could you enlighten
>me as to what OEMSR2 is? The way you are speaking, it doesn't sound

OEM - you know what that is.
SR2 - Service Release 2. All major clone makers now ship this release with their new machines. It contains many major updates - MSIE3, DirectX3, Mail, News, and much more. It's what I presently run on my machines - that and NT4-S.

>like OEMSR2 is a normal feature of Windows 95, it sounds like an add
>on for it (or at the minimum some special configuration of it).
>Regardless, I shouldn't have to do anything special with Windows 95 in
>order to get this basic functionality.

Didn't you get a driver disk from Diamond? Why are you unwilling to grab one from www.diamondmm.com, if this is such an issue for you? I find it very suprising - I stay in 65k colors 100% of the time, and the only thing I change is resolution sometimes (rarely).

>I realize that with the right drivers and the right extensions, that I could get this functionality quite easily. The point is though, that I need the "right" drivers and these extensions to do this under Windows 95. I don't need *any* drivers or extensions to do this with the Mac OS. I believe that is what the issue is (or was).

Suffice to say you are one of the only ones I've heard of to have this sort of problem.

>The simple fact of the matter is that a user shouldn't have to go through all this trouble when better solutions exist. As I've said before, does this really affect me? Not really, I rarely have occasion to change video resolution / bit depth. But it is one of the nice things about the Mac that I don't have to do anything special to have this capability.

...and the Mac doesn't ship with a WWW browser (well, 7.6 will, if you can stand CyberPuppy). Which would you rather lack? Me, I'd rather get _both_, which OEMSR2 has, but if I had to do without one, and didn't have the ability to get one, I'd do without the ability to change colors without a reboot and I'd keep MSIE3.

In other words - big deal, HTTP it. I don't know why your machine doesn't work like all of the other machines around, including mine, which probably has a similar chip in it, but you -do- have a solution to your problem that's staring you in the face.

If you don't know, then why are you spreading FUD?

I'd like you to name a current DOS-compatible card _without_ VESA. It's been a long, long time. The last card I remember using without VESA was a Compaq QVision 2000+ graphics card, for which DOS support was definately an afterthought (it was heavily optimized for Windows, at the expense of DOS speed), but even that used a 3k program, and bingo - it had VESA. Before that, I don't recall using a PC card without some form of VESA, except the DOS Compatibility Card I had for my Mac Centris didn't have VESA...but, again, a simple program took care of that.

>>With Win95 if you have a supported chipset you don't need an extra

That's certainly true. Where did I say anything to contradict that?
Answer: I didn't.

>>In all cases _something_ tells your hardware what to do, but it's in
>>the ROM BIOS or the core of the OS.

>Yes...something does. The Mac OS has the basic functionality of
>displaying all resolutions with all color depths built into the OS

...as does the PC for VESA modes and for any chipset built into Win95.

>Contrast this with the PC. The PC requires a special driver to
>utilitize any resolution or color depth above standard VGA (which I
>believe is defined as 640 x 480 at 16 colors). Windows 95 includes

The standard in DOS is VESA, which, as we've been over, is on modern
cards.

>many drivers for a variety of graphics cards/chipsets, but this does
>not mean that Windows 95 has this functionality built in...it still
>requires a driver.

The driver is built in. Whether you consider that 'functionality' or
not is word play.

If you have VESA (I'll take your word that this is really true, as I don't know myself). There's that famous "if" that is always popping up in the PC world.

>With Win95 if you have a supported chipset you don't need an extra
>driver.

Yes you do, the necessary drivers are just included with the Windows 95 CD-ROM. But they are still different drivers. If a new video card appears on the market that doesn't utilize one of the common chipsets that ship with Windows 95, your going to need a driver supplied by the manufacture to use any resolution/color depth beyond VGA.

>In all cases _something_ tells your hardware what to do, but it's in
>the ROM BIOS or the core of the OS.

Yes...something does. The Mac OS has the basic functionality of displaying all resolutions with all color depths built into the OS itself. No need for a special driver to use all available resolutions and all color depths supported by the video card.

Contrast this with the PC. The PC requires a special driver to utilitize any resolution or color depth above standard VGA (which I believe is defined as 640 x 480 at 16 colors). Windows 95 includes many drivers for a variety of graphics cards/chipsets, but this does not mean that Windows 95 has this functionality built in...it still requires a driver.

George is entierly correct in what he is saying. It is another example of one of the small, but numerous things that make the Mac more refined than a PC. How much weight this carries to the user can only be determined by the user. But it is still one other thing the Mac does better than the PC.

Josh

You wouldn't by any chance be using a Diamond based video card are you? Diamond is notorious for doing rather goofy things with their "standard" S3 cards.

The only redeeming fact is that Diamond is finally figuring out how to do support for at least Win95 and WinNT 4.0. If you are using a Diamond card, you should be able to download a "real" driver from www.diamondmm.com. Just make sure you know whether you have a Graphic, Video or 3D series of video cards.

Actually, these days you would be very hardpressed to find a non-VESA video card for the PC.

>Contrast this with the PC. The PC requires a special driver to
>utilitize any resolution or color depth above standard VGA (which I

It depends on the OS.
Some OSes are limited only to VGA/SVGA (640x480x16 or 800x600x16).
Others are capable of using the entire spectrum of the VESA specification--which I believe goes all the way up to 1280x1024x16.7 million colors (although, someone check me on that).

>Isn't this your home PC?

Nope...it is my work machine. At home, the only thing installed is
Windows NT Workstation 4.0.

The work machine has both Windows 95 and Windows NT Workstation 4.0
installed. It primarily runs Windows NT with an occasional reboot
into Windows 95 for various reasons (such as testing out video
resolution switching for posts to the newsgroups :-))..

>>Another funny thing...as I mentioned above, it asked if I wanted to

Possibly, but three different times...I doubt it.

>>As for OEMSR2 and QuickRes, I realize they solve these problems but

>OEMSR2 isn't an extension - it's Win95.

You'll have to excuse my ignorance...I'm unclear as to what OEMSR2 is.
I can't find a refernce to it on MS's home page. Could you enlighten
me as to what OEMSR2 is? The way you are speaking, it doesn't sound
like OEMSR2 is a normal feature of Windows 95, it sounds like an add
on for it (or at the minimum some special configuration of it).
Regardless, I shouldn't have to do anything special with Windows 95 in
order to get this basic functionality.

>>reason why this functionaliy couldn't be built into Windows 95 in the

>don't require a reboot. In any case, QRes solves the problem. Why
>you don't want to try it is a mystery to me. Does your Mac use *no*
>non-Apple extensions?

I realize that with the right drivers and the right extensions, that I
could get this functionality quite easily. The point is though, that
I need the "right" drivers and these extensions to do this under
Windows 95. I don't need *any* drivers or extensions to do this with
the Mac OS. I believe that is what the issue is (or was).

The simple fact of the matter is that a user shouldn't have to go through all this trouble when better solutions exist. As I've said before, does this really affect me? Not really, I rarely have occasion to change video resolution / bit depth. But it is one of the nice things about the Mac that I don't have to do anything special to have this capability.

Josh

If you are going to be an ass and close minded about it, why should I
waste my time?

An 060 may be too slow for MacOS, hell, a PPC is too slow for MacOS,
but for TOS and Atari apps it is plenty fast.

Price is all relative. perhaps this machine is worth more to a certain market than
a slower 1500.00 PowerMac is?

All the best,
Chris @ Computer Direct

Voice output has been around a long time; my Amiga had it in 1986. But you qualified this as "good voice output", and since I don't know what you consider good, I can't really argue with your point. I thought the Amiga voice output was quite decent, and it was certainly understandable.

Voice output has always been much simpler than voice input. Heck, even a piddle-dunk outfit like Creative Labs has been able to cobble together a voice output program; they ship one with all Sound Blasters these days.

> b) IBM's money: which they use for very good purposes (buying Lotus,
> getting NS/2).

However, there is serious doubt about the extent to which IBM will be willing to *commit* that money to the OS/2 cause in future. The evidence is that IBM is cutting the budget on OS/2, not increasing it. They've got lots of money, but they're investing it elsewhere.

> c) Lack of competition: Microsoft products do not stand a change, and
> until Apple get the NeXTOS done, they also are no challenge.

I assume that you mean that "Microsoft products do not stand a chance". You are aware, aren't you, that Win 95 has now sold more than 4 times as many copies in just a year and a half as OS/2 has sold in its entire existence?

Win 95 is the fastest selling software product of all time. But I suspect you mean "doesn't stand a chance technically", not "doesn't stand a chance commercially". All I can say about that is, IBM and Microsoft will get profit from commercial success, not from technical success. A lot of people have gone broke producing products which were technically successful but commercially failures. I don't know whether OS/2 is a commercial failure, but it certainly isn't as successful commercially as Win 95.

> Note that Java, NC, etc. is part of the research (Sun works with IBM
> so well, I think they should join forces or something).

I don't recall that IBM had anything to do with the Java initiative, except for joining it like so many companies did. Java came from Sun alone.

Buying Lotus was the worst thing that IBM could have done for the future of OS/2. This is why so many 3rd party developers are abandoning OS/2. They now see IBM as competition, and they likely feel betrayed by IBM. They also know that they are not going to be able to compete with Lotus, now that it has IBM's deep pockets behind it.

Not to get off the topic but,

Diamond releases drivers that just plain do NOT work. Any problem I've ever had with Windows 95 has always been some screwy company that wrote drivers that outright SUCK. I think Diamond finally has the drivers down for the Diamond Stealth VRAM 3000.   Be sure to get the latest release from their web site: www.diamondmm.com

Brad

>Voice output has been around a long time; my Amiga had it in 1986. But you

The TI99/4A had it well before that. And for that matter, a few kids games
ran on it with rudimentary voice recognition. The Voice output was quite good
though it had to be programmed in to use the speech synthesizer.

And IBM has had a similar program for OS/2 and DOS for some time called
Speech Reader. There are some web sites on it. The market is small though,
limited to those with disabilities primarily. IBM also has Screen Magnifier for
those
with sight difficulties. My, it seems IBM cares!

>However, there is serious doubt about the extent to which IBM will be
>willing to *commit* that money to the OS/2 cause in future. The evidence is
>that IBM is cutting the budget on OS/2, not increasing it. They've got lots
>of money, but they're investing it elsewhere.

Oh? Like starting a division to concentrate on Networking applications and OS/2?
Like hiring 30,000 employees at ISCC in 2 years, of which will push all IBM
products,
including OS/2?
Like promising 20+ enhancements to OS/2 this year, and a new version next year?
And after just providing a new version in 96?

Ah Steven, quit the FUD.

>I don't recall that IBM had anything to do with the Java initiative,
>except for joining it like so many companies did. Java came from Sun alone.

And working with Sun and funding the development of apps has nothing to do
with it? Nor making NC machines to use it? Or putting it into OS/2, AIX, VM,
etc.?

Steven, your memory is short or ????

Diamond 3400 XL Video using the generic S3 driver, you will need to reboot after screen resolution change.

Same card using Diamond's driver and OnControl utility, will change resolution and color depth on the fly.

>I await your reply, Tom.

I'm not Tom, but I hope the above was good enough.

>Wrong! Mac video cards are written to the Mac video spec or they don't work

Translation: You need to use the Macintosh Analog of a VGA card.

It's a good thing you warned the world about this.

We might have actually gotten the false impression that Macs
were now as expandable as PC's and capable of accepting all
those nifty PCI cards.

You've saved the open minded among us a lot of wasted time, money
and effort.

Now that we've exposed what a paper tiger that Apple Plug-n-play
is we can all feel secure in the knowledge that if we really want
the (new) mac enviroment, all we have to do is buy NextStep or wait
for GNUstep to be 'finished'.

PC: The Mac of tommorrow, Today! '-p

>at all. That spec has not changed appreciably since the advent of 24-bit color.

What? No 2D acceleration? No 3D acceleration?

That's one static rotting old spec there...

>I don't understand what you are getting at in the above paragraph. Please
>illucidate. Thanks.

The vast majority of PC video cards are as plug-n-play as any mac video card. At that level, the same system design idea pervades both.

Installing a new video driver is all point and click.

The original release of Windows95 includes drivers for multiple frame-buffer cards. I found ones for the STB dual and quad. There may be more but, I didn't check any farther.

Just point and click your way to the name of the driver, put in the installation CD (additional, but trivial step) and you've got 2 or 4 distinct displays.

Fortunately, Windows functionality is not merely limited to that which BillyBoy ordains.

Think of us as EastAsia.

(although it's hard to keep them straight really) '-p

Thanks.

Unfortuantely, I seem to have lost the ability to start documents from the
command line if I use 4NT.

"start blah.txt" or "blah.txt" no longer seems to work. :(

Sigh.

It's a hopeless battle. There will continue to be FUD floating around the 'Net about ehich chip is better.

Why is PowerPC superior to Pentium/Pentium Pro?

1) More of a future. CISC is dying, and the PPro's double-die was incredibly sophisticated. The next iteration will have to be even more difficult.

2) Transition is already done. There will be yet another wave of upgrade mania and incompatibilities gripping the PC userbase when Intel finally migrates to RISC to stay competitive. This will cause even more confusion than exists now in the three-OS "Windows" market.

3) Higher performance in the very near future. 300 and 530 MHz PowerPC chips are currently available, and major leaders in the computer industry are rushing to use them.

4) NeXT is the new Mac OS. The next generation of the MacOS will be more stable, easier to use, more refined, and more powerful than anything on an Intel chip, will be running on faster, more efficient, RISC-based PowerPC chips, and will offer considerably more "native" applications than whatever OS MS is offering.

Facist & Cowardly. You mean, besides the fact that apple had to

good sense to document how they were going to do cards? Let's face it, I have yet to be able to go a solid week, without hitting some problem with Plug & Pray. Apple specified which cards would work and how they would work when they introduced the nubus. As for the rest of the PCI stuff, remember how backward the i86 system is.

It is amazing that any cards work. Apple may not be at the head of the pack with OS software, but their hardware is much better then the PC's that are out there (and I am writing this on a pentium pro 200).

]
]   All of this is rather easy to do when you so brutally restrict
]   what the system will accept. You're really lowering the bar,
]   nothing more.
]

Actually, the MacOS accepts a wide variety of video hardware. The only restriction is that a device driver is provided that provides interfaces to set the resolution, refresh rate, bit depth, color tables, etc. In addition to the many various NuBus and PCI graphics cards supported, Apple develops new and different video hardware with new generations of Macs and PowerBooks.

]   A PC can use Scanners and 3D boards that simply wont work with a
]   Mac, no matter how hard you try.
]

Generally, this is because Mac drivers are not provided by the manufacturer, not because of some restriction in the MacOS. Unless, of course, not supporting Windows drivers is considered a restriction :)

]   If PC hardware were so constrained, PC integration would be no
]   less difficult.
]
] >INSTANTLY, and EVERY TIME!!!! Try that with MS 'Plug-n-Pray'.
] >And, if its not so remarkable, how come PCs can't do it
] >reliably, and how come they left it out of NT altogether?
] >
] >"Enquiring minds WANT to know"!
]
]
]   Why? Because PC's support a greater diversity of hardware, a
]   greater diversity of bus options and aren't merely limited to
]   cloning someone else's spec.
]
]   They aren't merely limited to IDE boards, VGA cards, Sound Blasters
]   and the like.
]
]   Windows Plug & Pray attempts to achieve much more than the Apple
]   version ever dreamed of. The Apple version is nothing more than
]   a clever way to stack the deck. Apple has ordained what it will
]   support and left the rest to rot. There is nothing remarkable in
]   this restriction. When held up to the light, it acutally looks
]   rather fascist and cowardly.
]

As far as video display cards, video digitizers, sound cards, SCSI cards, and networking cards go, I don't know what Apple has done to stack the deck and left developers to rot (unless we're stacking the deck by not supporting windows device drivers). Apple itself has developed many different versions of the above hardware in our own products (we've even been dogged for changing our hardware too much) and supports an even greater array of 3rd party hardware, all with plug and play (I assume your use of "Windows Plug & Pray" was a slip).

]   What computer was born in 1984?

  Wasn't the PC born in 1981? Of course, the PCs and Macs today are quite a bit different that then.

I don't think the point was that Windows was limited to C: and D: drives as far as non-system drives is concerned, but Windows does have to be installed on a Primary partition. And since only one primary partition can be active at a time, that means it is C:. You most likely wouldn't have a removeable drive as your primary boot drive, therefore that drive would be D: or E: etc. OS/2 on the other hand can be installed on any partition using bootmanager (but HPFS can't be installed on a removable drive..at least not without some magic tricks.)

The Mac doesn't use drive letters, so the Mac System can reside on any drive, even a removable drive. You could plug your drive into another Mac and tell it to boot the system from the new drive and you are in business.

If you tried to do this on a Windows PC, the new drive would most likely not be C: and therefore WOULD NOT BOOT.

>Wrong. Mac Video is NOT VGA! Not only that but video plug-n-play

The PC heads think VGA is a default 640x480 screen with 16 or 256 colors.

But that is a RESOLUTION.

Macs use a linear addressing video buffer from the very beginning if I recall,
and if I recall, VGA requires paging.

Ore use an x-node SP/2 with HACMP for on-site takeover and HAGEO
connected by ATM-network for OFFSITE take over.

So is OS/2 for mine.

I still think there has to be some code in the card. It can easily patch the
trap tables, but I'll let someone more familiar with this tell me.

Yes it would need driver or extension or whatever you want to call it.

>
>   It makes a PCI version of that card actually.
>   Since the current macs claim to be able to use PCI card's,

How would any OS handle a card that was not designed for it either inherently or through the use of driver?

>
>   This should be the case regardless of whether or not that

Supporting the various Quickdraw functions is a lot more than just supporting a dumb frame buffer.

> In other words: Mac Video Cards are plug-n-play so long as they
> conform to the Apple equivalent of VGA.

Mac video cards are plug-n-play as long as they conform to the MacOS's guidelines just like a card made for the PC must have drivers that conform to the Window's spec or whatever other OS you're running.

Macs don't need drivers for basic functionality. They can take advantage
of graphics acceleration without. Some cards need drivers though for
things that go beyond the Quickdraw spec.

>   Now that we've exposed what a paper tiger that Apple Plug-n-play

A card has software on the card itself to interface with the QuickDraw
engine

>   What? No 2D acceleration? No 3D acceleration?

The card takes advantage of acceleration the same way it does with Windows,
by accelerating the graphics routines.

> >info required for anyone to write software or build hardware for the
Mac.
> >You'll be surprised how little the Mac video spec has changed over the
> >years.
>
>   This is supposed to be a badge of honor?

If it was done right the first time yes it is. But Quickdraw 3D has been
added to the spec the cards do take advantage of them.

>   Fortunately, Windows functionality is not merely limited to that
which
>   BillyBoy ordains.

This whole argument is pointless. The driver's for the Mac on the card and
the Windows's driver's are installed separately. There is really know
difference in the functionality.

>
> ==Thanx==
> ===Ben===

Ben, I used to hate it when people said that Atari was dead. But now
its true.
There is no more Atari computer company. Your 'Multisync Switch Box' is
not
only totally unnecessary on new equipment (the need for such was just a
way to
sell monitors anyway), but you can make one yourself with a small platic
box
and a rotary switch. Total cost about $5-$10 and 30 mins to an hour of
work.
So, forgive me if I'm not floored at the loss of the WonderTech and his
super switch box.

Toad prices suck. All Atari prices such. A Pentium 90 w/512K cache,
dual EIDE
controllers, dual 16550 UART serial ports, parallel, full PCI, etc, is
$250!
Add a case, hard disk, monitor, and keyboard - all of which can be had
at your
local sidewalk sale for pennies, and you have a decent machine. Add
Linux for
an OS and you never have to look at MicroSloth either. I hate Intel,
but the
ST just doesn't have the power, and its WAY too expensive to upgrade.
That's
why I dumped the Atari 8-bit - upgrade was too expensive. Now there
isn't any
cheap Atari to upgrade too.   Sure a Hades would be great, but if I was
gonna
buy another unsupported piece of hardware, I'd get a BeBox - at least
that has
some upgradeability and a decent price point.

CYA,
Evan

ATARI PROTOTYPE AUCTION #1: (UPDATE #1 12/29/96)

The following RARE items are available for auctioning.

RULES: Bids start at specified price and will go up in $10 increments. Updates will be posted daily to all bidders. Auction will go until Jan 10th 1997 and will then enter the GOING, GOING TWICE, GONE stage. All bidders who make it to the GONE section of the bidding are responsible for shipping costs. All items will be shipped PRIORITY ONE MAIL. Please don't bid unless you are serious about buying. All items are sold "as-is" and there will be no returns and/or refunds. No items will be shipped until payments are received and cashed.

Atari SALT Diagnostic Module: Enclosed in an Atari 850 interface, has 1 Serial SIO port, 4 Atari RS232 ports, power input, an RCA plug where the Parallel intreface would normally be, and 2 14 pin chip sockets, an HP seven segment ultra-bright LED display and reset switch. Unit powers on and doesn't cause any Atari that was hooked up to it to freeze.
Salt Diagnostic ROM or disk software required to activate and use this unit (NOT INCLUDED), picture available on my web page upon request.
(3 Available) Minimum BID: $50.00ea.

BID: $50.00 MKyle

Atari XL Salt Diagnostic Module: Enclosed in an Atari 850 interface, unit has PBI cable comming out of right side SIO connection cut-out of 850 module for testing parallel bus interface.
Salt Diagnostic ROM or disk software required to activate and use this unit (NOT INCLUDED), picture available on my web page upon request.
(1 Available) Minimum BID: $75.00

BID: $75.00 MKyle

EXTREMELY RARE: Atari 6402A Prototype Motherboard (only 3 exist!!!)
Prototype motherboard, apparently a test bed which has all the same components contained on an Atari 1450XLD "TONG" version motherboard including disk drive controller area, modem area, SC-01 voice synthesiser, Parallel Bus Interface. This unit has ports positioned on all 4 sides and does not appear to be a "commercial" product but appears to be more of a test design to condense the Atari 1450XLD TONG motherboard down to about 1/2 the size, (unit is NOT functional)
Minimum bid $120.00
Image will be posted on my webpage upon request

BID: $120.00 MKyle

Atari XE Game System 8 port multicart prototype board:
A prototype test board which may have been a pre-design idea to allow

the XE game system to contain and select up to 8 cartridges (this of course turned out to be built in BASIC and MISSLE COMMAND in the released version) The board is about 8" by 12"
Minimum Bid $50.00
Image will be posted on my webpage upon request
BID: NONE

Atari XEP-80 Prototype:
Atari Corp design prototype of the XEP-80 system.   Design consists of a mainboard, daughter card, DB-25 connectors and Atari joystick interface cable, this unit has never been tested and I am not sure if the current commercially released XEP-80 software will work on this pre-design prototype.
Minimum Bid: $75.00
Image will be posted on my webpage upon request

BID: NONE

Make all bids and requests for images to:

They would understand it all too well, given full disclosure.
They used to refer to such things as VGA and EGA. If they
want to so restrict themselves in the name of ease, they have
the option to use such things.

However, they would all laugh in your face if they knew that
such things are what Mac Plug & Play is truely limited to.

The accomplishment, in reality, is much less impressive than
it would appear (Mac Clone & Play).

So much for the open bus standard...

Thanks for bursting our bubble. We thought now that one card
could service the same need on a PC, an Alpha clone, an Atari
clone (mebbe Amiga clone too) or even a Mac.

You've just reduced the situation to where it used to be.
Macs require their own special hardware.

>
>>   What? No 2D acceleration? No 3D acceleration?

Since MacOS was not designed with ''oddities'' like the CL 5434 or
the ATI Rage II in mind, it wont be accelerating anything.

Plug & Play will disapear.

Precisely. In this manner, the fact that Windows 95 comes delivered
with driver support for multi-monitor video cards makes that functionality
just as 'built in' as it is for MacOS.

>
>>
>>   This should be the case regardless of whether or not that
>>   particular PCI card is nothing more than an Uber-VGA card.
>>

It would depend upon the hardware actually.

I also suspect that this 'standard' is just another instance
of VGA++. Everyone is essentially cloning the same hardware specification.

>

>> In other words: Mac Video Cards are plug-n-play so long as they

>
>Mac video cards are plug-n-play as long as they conform to the MacOS's
>guidelines just like a card made for the PC must have drivers that conform
>to the Window's spec or whatever other OS you're running.

Precisely. The MacOS requires conforming hardware. Everyone else merely requires a conforming driver interface. It is not too difficult to see here how complexity and choice are being simultaneously restricted. One gains at the expense of another. Options and flexibility are sacrificed for ease. In the end, what is achieved is qualitatively and quantitatively different.

MacOS plug & play is not a superset of Win95 plug & play. That should be well understood and freely admitted. Anything else is pure fraud.

Users should know exactly what they're getting. They should be capable of making informed choices. The Mac tendency to hide important details quite interferes with this.

If anything: Win95 plug & play attempts to be a superset of the Mac's.

Actually, VGA is a low level video spec. that also happens to include standard resolution and color depths.

Such cards are register level compatible with a standard driver that comes as a part of the BIOS on PC motherboards.

The design paradigm at work is identical to the one that drives Mac 'Clone & Play'. One driver ships with the machine and all hardware is expected to run with that driver.

One spec has a few more frillsl than the other but, that is it.

You are delving into idiot areas....

Anyone who has used both machines knows that the Macs multi-monitor support is faaaaaaar superior to windows. <period>

With a Mac you can plug in multiple different off-the-shelf monitor cards, and have a virtual desktop of the union of those monitors - arranged as the user wished, and use them for various things. The system allows apps to request certain things - like highest res., most colors, etc. and work accordingly. The system also auto-dithers images across monitors, and knows which is the primary monitor.

The PC way is that App writers can try to talk to every known driver out there to try to figure out the same thing, and then features will only work one app at a time. Some cards support multiple monitors of the same resolution... but the system doesn't know shit about it. (can you say cheesy hack?!)

The Mac was is far superior. <period> MS is lazy, and implemented a bad (limiting) design.... and users pay the price.

> Precisely. The MacOS requires conforming hardware. Everyone
> else merely requires a conforming driver interface. It is not too
> difficult to see here how complexity and choice are being
> simultaneously restricted. One gains at the expense of another.

Nope... people add by making their cards compliant with certain system restrictions... just like windoze. There are often FEWER restrictions on the Macs than on the PC's. So where is the cost?

Apple designed their stuff better... it took longer up front, and more money... MS just hacked it and called it "good enough".

> Options and flexibility are sacrificed for ease. In the end, what
> is achieved is qualitatively and quantitatively different.

Yes... the Mac is better and more versitile, and works more the way people would like it to.

> MacOS plug & play is not a superset of Win95 plug & play.
> That should be well understood and freely admitted. Anything
> else is pure fraud.

Superset? No... Win95 is a cheap hack that is meant to make up for a bad initial design (or lack of an initial design)...

The Mac is well designed, with versitility in mind.

Call Mac PnP a superset of Win95 PnPray is like calling a BMW a superset of a Model-T (with electronic ignition and after-market air-conditioning bolted on). Sure they both have wheels and a motor-but one is designed far superior than the other.

>   If anything: Win95 plug & play attempts to be a superset
of
>   the Mac's.

It may try... but it falls far short of success.

Mac PnP works.

What you mean is that you desperately HOPE that some TOS advocates
will claim this because you might actually have a good point and an
argument that might win for once. I know very little about NeXT but
I have seen bit of it in use and have only heared pleasnt things about
it. I didn't think that MacOS was going to be based upon it but I was
under the impression that NeXT was being developed for the PPc range
which I believe to be a better idea.

Quickdraw is no more a low level design spec than GDI or DirectDraw.

> Without a driver api, 3rd party drivers become somewhat difficult.

There is a driver API -- despite what some Mac users in this group seem to believe.

>

Yes, with the proper extensions. Writing an extension to support various types of hardware is well-known and well documented.

The VGA and EGA specs did not provide OS specific routines to allow advanced graphics handling. A Mac compatible card can and does accelerate Quickdraw functions just like a PC graphics card provides GDI accelerations. There is no difference.

No kidding.
Given that Apple has dictated exactly how the hardware must be
designed since 1984, I would be incredibly surprised if Macs didn't
support multiple monitors better than Windows/Win95/WinNT/OS/2.

However, this whole thing started because someone made the comment
that Windows/Win95/WinNT did not support multiple monitors. Nothing
about supporting it "better" than a Mac.

Windows/Win95/WinNT supports multiple monitors <period>.

By labeling someone based upon their nation of origin, you are engaging
in two of the most base of logical fallacies - nationalism and
regionalism. Neither contributes to your logos.

Perhaps, but TOS _IS_ superior in some key areas, including hardware
efficiency and resource allocation.

It certainly isn't superior in support or speed, but, as you
consistently fail to notice (or are retarded by feeble neurons from
realizing), different people use different computers for different
reasons. So for many people, TOS will be superior to MacOS 9 running on

a quad PowerPC 609e 100 GHz machine.

```

Got to love those Democrats and Republicans - claiming to be so
different, yet running two candidates whose positions differed in one,
insignificant area.

Unbelieveable.

      This is quite a different story than the MacVocates are telling.
      With them, video hardware either conforms to the low level
      design spec or it gets left out in the cold.

      To them, the concept of installing a driver of any kind, in any
      way is completely alien. They rail upon this as a Win failing.

This question is fielded to actual users:
Can you expect MacOS plug & play to work when a 3rd
party driver is required? Will it work if the low level
hardware
spec is not adhered to?

>supporting windows device drivers). Apple itself has developed many
>different versions of the above hardware in our own products (we've even
>been dogged for changing our hardware too much) and supports an even
>greater array of 3rd party hardware, all with plug and play (I assume your
>use of "Windows Plug & Pray" was a slip).

I have no sad dellusions. I feel no need to lie to anyone.

Must still be more TOS machines around than NeXT machines. Maybe the NeXT
machines are just shy and keep well hidden!! :)

I still reckon that no-one, INCLUDING Apple, know where their next OS is
gonna come from...

Yes, will they? Where?

I personally haven't dealt with Toad since I met the Troy's at an Atari show several years ago. They had a bin full of 8-bit carts that were selling for $10 a piece (even though you could find them elsewhere at the show for a buck or two). Anyway, I found a rare cart in there and when they saw me looking at it, Mrs. Troy literally snatched it out of my hands from across the booth and rudely told me it wasn't supposed to be in the bin! I'd never had someone do this to me before or since, even with all the hostile people I've dealt with at flea markets over the years, and I was quite pissed! There could have been another way to tell me the stupid thing wasn't for sale...Anyway, I appreciate that they support Atari after all these years, but get real...they have always charged close to full retail for EVERYTHING, since the very beginning. How the hell did they survive this long dealing Atari wares when all the good vendors fell by the wayside?

Just my 2 cents worth...

Greg

It seems the Mac also has no small letters and it's keyboard sucks
(see how often the exclamation mark shows up above).
```

>But it still holds years of advantage over Win NT and DOS7 & Win95.

I have yet to see any of those systems making it's user unable to
avoid multiple exclamation marks and articles in (mostly) all caps.

Compared with Win NT and Win 95, MacOS is much worse. That's why
Apple bought NeXT - to get in advance again.

The Amiga doesn't always insist on closing all windows-this generally happens when you have a screen behind the WB screen. If you just have some WB windows open it will generally redraw the screen without any trouble. Windows 95 makes you reboot to change screen resolution. As far as I can tell, you can't run multiple screens in different resolutions in Win 95, something which the Amiga does quite nicely. I've had to buy a clone laptop for school, 120mhz Pentium, 24 megs of ram, 1 gig HD, 6x CDROM, 1meg video ram (SVGA) 16 bit sound card, etc. Win 95 was preinstalled. I've used it for a couple of months. I'm still waiting to be wowed by this machine. I've run it out of memory, browsing the Web with one or two apps in the background, something I've not done with my 18 meg 3000, As for Win 95 memory protection, this is something I'm glad it has because it really needs it. I will say Win 95 is much better that Win 3.1, but then again AmigaDOS 1.1 was better than Win3.1.

Perceptually, this clone is not any faster than my 030 3000. I know that it is many times faster hardware wise, but in everyday usage, the 3000 opens screens just as fast, I download and Web browse just as fast, it prints just as fast on the same printer. Could I run 2 3D renderers, print in letter quality, download at 28.8, decompress files from CD to RAM:, all at once on this clone with out noticing any system degradation?1 I seriously doubt it. Could I do this on my 3000? Hell, I don't know, I did it on my 030 2000 with 9 megs o' ram, testing a shareware task scheduler.

Win 95 has a long way to go. The only advantage I can see for the clone is the variety of software, and you still have to separate the wheat from the chaff...

I have on my system right now:

2GB SCSI Hard Drive (C: and E:) C: is regular FAT with 95
on it, E: is NTFS
Syquest EZ135 Internal EIDE drive (D:)
Iomega Jaz 1GB Removable SCSI drive (F:)
Phillips CD-Recordable SCSI drive (G:)
Mitsumi EIDE CD-ROM (H:)

They all work just fine under NT4.0, so that is all the
proof I need!

I can boot off my C: drive, the EZ135, or the Jaz drive if
I want to.

If I every need 4 monitors at once, I guess I will feel
left out! :)

I have used Linux only out of curiousity. I feel one should know about the
various OSs available, even if only using one.

In the mid-80's when Atari was using the slogan "Power without the Price" It was true. You couldn't buy a better system for the money. The problem is that the prices on Atari hardware became stagnant, while hardware prices in the PC world dropped rapidly. For instance, in 1992 Atari released the Falcon '030 (1 meg, no HD) for $799. Today toad is still selling the MK-I falcons with the same specs for... $799. In 1992, $799 might have bought you a 286 or 386 system with 1meg and a small HD if you were lucky. Now you can buy a low-end Pentium-class machine with 16meg RAM and a 850meg (or better) HD.

Add-ons are similar. For over $150, you can take your 8mhz ST to 16mhz with an Adspeed. For about $50 you can replace a 66mhz 486DX2 with a 133Mhz 5x86 CPU on a PC.

I would love to have an Atari clone that was as powerful as my PC (like one of those
Medusas or Hades machines) But at $3500 for what is equivalent to a slower Pentium at best, I just can't afford it. :(

And visa-versa. I run Win95 and Linux, and find them both to have their pros and cons, but if I had to choose one, I would choose Win95.

Now, some Amiga-centric person is probably out there saying, "Gee, these PC losers need multiple OSes to get what an Amiga owner has in one OS", and to that person I say, "I would choose either one of them over AmigaDOS". I have all three, and my computing time is about 60% Win95, 35% Linux (intel), and 5% AmigaDOS. OS/2 was down to 0%, so I deleted the partition.

Why wouldn't you browse the web just as fast? The modem would be the limiting factor.

> it
> prints just as fast on the same printer.

Again this is a i/o bound task that wouldn't be significantly affected by the processor. Unless you are using a printer that depends on the CPU for rendering.

> Could I run 2 3D renderers,

degradation?1

That only means that all of your background tasks are being starved for CPU time.

I guess, then, that not many of them have written video drivers :)

> To them, the concept of installing a driver of any kind, in any
> way is completely alien. They rail upon this as a Win failing.
>

This probably stems from the fact that one part of the spec of NuBus and PCI is a method of providing video drivers in a card ROM. Video cards are not required to do this, but, if they do, the user does not have to install a driver.

Another factor is that Mac users typically do not need to select the driver to use with most types of cards. Usually, the most that is needed is to run an installer script on a flopppy. The OS and sometimes the driver will determine if the driver's hardware is present. If it is, the driver is loaded. If it isn't, the driver is not loaded. Thus, you could, theoretically, have hundreds of video drivers installed on your system, plug in a video card that requires one of those drivers, and the correct driver will load and run the video card; the user will not have to select which driver to load for the card.

> Without a driver api, 3rd party drivers become somewhat difficult.

True. I'm glad we provide driver api's for many device classes.

> Can you expect MacOS plug & play to work when a 3rd
> party driver is required? Will it work if the low
level hardware
> spec is not adhered to?
>

There are a few levels to plug-n-play. The first is being able to write a driver and have it or the OS be able to tell if the hardware for the driver is available and automatically load the driver and correctly configure and operate the device. The only requirement for the user is to run some installer script on a floppy -- no setting IRQ's, com ports, SCSI ID's, etc. The second level of plug-n-play is all of the above with the driver being loaded from the hardware device itself. In this case, all the user has to do is plug in the hardware, and the driver software is automatically installed. This level of plug-n-play is possible with NuBus, PCI, most hard drives (read off the media), FireWire (we're working on Open Firmware specs for FireWire), and others.

As far as the low level hardware spec goes, a PCI video card should adhere to the PCI spec. If it does and has a video driver in card ROM or installed from a floppy, it will work. If it doesn't conform to the PCI spec, all bets are off.

This is not actually correct. Perhaps you meant to say "Mac video card 'drivers' are written to the Mac video 'driver' spec or they don't work." That statement is correct for both the Mac and Windows.

Well, they are. But, just as with some applications, 3rd parties don't neccessarily support the MacOS. It's merely a matter of software drivers, not hardware.

>
> Macs don't need drivers for basic functionality. They can take advantage

> things that go beyond the Quickdraw spec.
>

As for video cards, Macs do need drivers for basic functionality and graphics acceleration. On most video cards, however, a driver is provided in the card ROM, so users don't need to install any drivers from a floppy.

>
> > >info required for anyone to write software or build hardware for the

> > >years.
> >

As far as video hardware goes, it has changed quite a bit on our own systems. Apple doesn't mandate any video hardware spec other than providing a basic frame buffer. As far as the video driver spec, a lot of it has remained the same, but a lot has been added such as support for sleep, graphics acceleration, and hardware cursors.

>

From what I've heard, multi-monitor support in Windows 95 is dependent upon support in the driver and possibly the video card itself. If a 3rd party does not implement extra code in their driver, multi-monitors are not supported for those cards. I've heard that some Windows video drivers support multi-card multi-monitors if you have more than one of the same video card with each set to the same resolution and bit depth.

The difference on a Mac is that multi-monitor support is built in to QuickDraw; it is not a function of the video driver. Thus, on the Mac, you can install multiple video cards from different vendors, set them to different resolutions and bit-depths and have it all work. Windows can span across the various screens and will display correctly even if the displays have different bit-depths.

> >
> >Supporting the various Quickdraw functions is a lot more than just
> >supporting a dumb frame buffer.

Actually, Quickdraw assumes a dumb frame buffer unless a card has hardware acceleration and provides driver software to support the acceleration.

>   I also suspect that this 'standard' is just another instance
>   of VGA++. Everyone is essentially cloning the same hard-
>   ware specification.

However, the dumb frame buffer hardware may be implemented in many different ways. The only video card memory that Quickdraw directly accesses is the frame buffer. Quickdraw makes driver calls to get the frame buffer base address, resolution, bit-depth, row bytes and to set the resolution, bit-depth, etc.

> is achieved is qualitatively and quantitatively different.

I've mentioned this on another thread, but this thread is getting more
attention so I'll clear things up here too. The MacOS only requires
conforming driver software, not hardware.

I know not the people of which you speak, but as a business man myself,
I would suggest that the answer to your query lies in the question.

They charge what the market will bear, and in so doing maintain the
viability of their endeavour. Or to turn it the other way round, the
ones you like because they charge less disappear because in keeping
you happy they are themselves unviable in the long term.

IBM didn't "drop it", but merely suspended development for at least a year.

Brian-Roland Miller <brmiller@tiac.net> wrote:

>It certainly isn't superior in support or speed, but, as you

Actually TOS is superiour to NeXT OS in terms of speed. I think what you may have been referring to is hardware speed. In which case, TOS based machines can and do compare quite nicely.

The rest of this message is not aimed specifically at you Brian...

The combination of an efficient OS and efficient application programming make so called antique (by Peter's standards anyway) hardware like an 040 or 060 perform faster than MacOS and applications on the fastest PPC.

The fact that even Apple doesn't seem to know where it wants to go today,
only sets Apple up for more criticism by non Apple users as well as Apple users.

There is absolutely nothing wrong with a company that changes business plans part way through a year. In fact, this is a good sign, a company that is flexible and open minded and willing to change with the market is a healthy company.

However, a company that flip flops and changes it's mind several times during the year looks to be indecisive and gasping for air. This is exactly the problem with Apple today and the NeXT announcement only serves more fuel to the fire.

We can all comfort in knowing that MicroSoft will not let Apple die since that would leave MS in a risky situation with the Justice Dept. If Apple dies, MS might be forced to become smaller.

1997 will be a big year for personal computing. 1997 will an enormous amount of innovation in computing and .... believe it or not ....
the post office!

I wish everyone a Happy and Prosperous New Year!

All the best,
Chris @ Computer Direct

From what I have read, parts of Copland will be grafted over Next Step. The remaining unix that the user sees will be eliminated. The end product will hopefully be a nice OS when its ships later in '97'. By that time a 300mhz PowerMac can be had for $2000 or less.

Also, now that the Be OS will not be adopted, I am sure there is an incentive for Be to finish the OS and get it out and let the market forces decide.

Very true that many will think that TOS will be superior in their minds. People should use whats best for them. My only beef when they start to exagerate and become deluded in regards to other platforms.

I'm curious; what exactly is those 5% AmigaDOS. If you loathe AmigaOS
so much, why don't you jump ship completely ?

Who said anything about loathing it?  I just think it's highly overrated
and it doesn't suit my purposes much anymore.  I am tired of the slow
file system, the lack of real DIB, the extremely inefficient
multitasking of the WorkBench, and the hardware shortcomings.

What do I use the Amiga for?  I wrote a few MIDI programs for it that I
occasionally use, and fx modules I wrote for ImageFX using the devkit.
To tell you the truth though, most of the time I use it these days, it's
to test someone's claim about how much better the Amiga is at doing
something.  And I almost always get different results for some reason.

Toad is about the ONLY company tha still regards Atari computers as real computers. Most of you guys still think of Atari as nothing more than a game platform and sell them as a simple game server. Its the users of Atari computers who have driven the prices down in private sales. A guy buys a 1040 for $700 and a few years later nobody will pay more than $50 for it. C'mon now folks, the hardware is much better than that. These are REAL computers, not nintendos.

Toad recognizes this fact and sells their stuff as real computers. They also stand behind their sales if something goes wrong. Toad currently sells a 1 meg 1040 for $199 and thats a very good and realistic price, but if a guy advertised one here for sale as an owner looking to sell his stuff, most of you would say thats too much for a 1040. SO admit it folks, either you have real computers or nintendos for sale in this group. I say that Atari made real computers and I bought them as such and will sell them as such when the time comes.

Has anyone seen the 20th anniverasary special edition Mac code name Spartacus?
If not, load up your web browser to www.macweek.com or macuser.com.

I want one but can afford the reported $9000 price tag. However, I am
excepting donations.. So send your unwanted pocket change to me...:-)

```

```

Here is some information that I got from www.specbench.org:

```
  Model Name: Alder
                CPU: 200MHz Pentium Pro Processor
                FPU: Integrated
   Number of CPU(s): 1
      Primary Cache: 8KBI+8KBD
    Secondary Cache: 256KB(I+D)
        Other Cache: None
             Memory: 128MB (60ns fast page)
     Disk Subsystem: 2GB ST32550W
     Other Hardware: AHA-2940W Controller
          SPECint95: 8.09
           SPECfp95: 6.75

         Model Name: PowerStackII Pro3000/200
                CPU: 200 MHz PowerPC 604e
                FPU: Integrated
   Number of CPU(s): 1
      Primary Cache: 32KBI+32KBD on chip
    Secondary Cache: 1MB(I+D) off chip
        Other Cache: None
             Memory: 128MB EDO
     Disk Subsystem: 2x2GB
     Other Hardware: None
          SPECint95: 8.00
           SPECfp95: 6.31
```

So, according to SPECint, the Pentium Pro is 1.1% faster than a similarly clocked 604e. According to SPECfp, the Pentium Pro is 7.0% faster but the 604e compiler was generating IEEE precision instructions and not it's own faster and more precise instructions. Summing it all up, the only bechmark that favors the Pentium Pro indicates only a marginal difference at the same clock speed. Other benchmarks, such as BYTEmarks, decisively favor the 604e. Remember, also, that 250MHz 604e chips are shipping and the fastest Pentium Pro is only 200MHz.

Besides someone totally brainless, noone will claim an overall superiority of TOS when comparing it to NeXTstep. TOS is slim and hardware efficient, but in all other areas NeXTstep beats TOS hands down.

Thorsten

>in Windows NT 4.0 and Windows 95 (unless you are using some old hardware
>that hasn't updated its Windows 95 driver).

After spending hours searching for a way to set an environment variable under 95 similar to NT, without using the autoexec.bat file, I have come to the conclusion that the autoexec.bat file is still a very important portion of the win95 system.

NT doesn't suffer this problem, and environment variables are easy to set, alter, or delete, as long as you can actually get to the portion of the variable you need. Try deleting a part of your path variable included in the SystemPath. I spent 5 hours hunting for it, and finally reinstalled to remove several entries in the path that were installed to the %SystemPath% variable. Reinstalling everything was quicker. The registry will kill NT as far as enterprise systems are concerned. Everything is difficult with respect to it. Give me the simple 130 line config.sys file and total control anyday. :P

Try it sometime.

Ron

newsgroups: comp.sys.atari.st,comp.sys.atari.advocacy,

I have a 40meg external mac HD, and would like to connect to my 1040. Is
there a standard cable that would work? What would be the best
driver/editor software to start 'er up once I get a cable?
Also, I'm looking for the best way to download software from my mac, and
transfer it to the ST. I've had some success after unzipping, and saving to
a 800K DOS disk, but looking for a more reliable system.
I've hooked the ST to my mac with a null modem cable before, and it
transfered ascii just fine. would this be a better solution for transfer?

Thanks in advance,
Mark

Yes, but "basic" in terms of what a PC and a Mac consider "basic" are completely different. For example, the Mac considers a GUI to be "basic", PC's don't even come with a CLI unless you boot one.

Sad to see you know nothing about OpenFirmware. OF requires drivers on the cards or in the machine, but allows the card to identify itself, and what it needs. Someone still needs to write the drivers, or did you think the Intel code would run on the Amiga without any changes?!

>   You've just reduced the situation to where it used to be.
>   Macs require their own special hardware.

PCI cards with OF require custom drivers for _all_ of the machines they support. They typically come with only PC/Intel support on the card itself though, and many times not even that. It's totally possible to make a single card that plugs into everything, but most vendors are too lazy.

Not really, I've yet to install one that didn't need a disk to be loaded. On the other hand most of the Mac ones work without such a disk.

> >Mac video cards are plug-n-play as long as they conform to the MacOS's

No, it doesn't, at least not on OF 2.1 cards (which all PCI cards are supposed to be). Just like their PC cousins, they can have the drivers on the card or the drives somewhere. The difference is that the main Mac drivers are a lot more flexible.

> else merely requires a conforming driver interface. It is not too

They're "hidden" because you don't need them.

> If anything: Win95 plug & play attempts to be a superset of
> the Mac's.

True, but what of it? In my last call to Gateway they made me turn off P&P on the ethernet card because it made it stop working. That's really showing the concept of MS's P&P at it's best I'd say.

Depends on which password you are talking about. I assume this guy is
merely referrnig to the fact that most people don't bother to change
certain system user profiles (QPGMR springs to mind) and thus have a
rather large gaping hole in their security. I think he is right.Don't
bother trying any of my AS/400's though :-)

The Mac is no different. It just hides details from you and restricts your options.

Furthermore, your information is just plain WRONG.

For quite some time it has been rather difficult to NOT get a Microsoft GUI bundled with a computer.

Although, it is nice to have other options.

1 competing commercial PMT 32bit OS w/ GUI
2 competing commercial Unixes (PMT,32/64bit,GUI...)
3 freeware unixes (PMT,32bit,GUI...)

I am just not impressed with silly buzzwords. What you describe is
nothing more than a ROM BIOS. It is also quite unnecessary.

>what it needs. Someone still needs to write the drivers, or did you think
>the Intel code would run on the Amiga without any changes?!

I was never stupid enough to even consider that.

Although, despite such burdens, both Atari and Amiga have been
using PC expansion cards for quite some time. Before Macs even
considered it, Atari/Amiga were using cards that only came with
'PC/Intel support'.

These platforms don't limit themselves to 'VGA' functionality either.

>
>>   You've just reduced the situation to where it used to be.
>>   Macs require their own special hardware.
>
> PCI cards with OF require custom drivers for _all_ of the machines they
>support. They typically come with only PC/Intel support on the card

An open bus standard becomes meaningless if the card has to be
in any minutest measure, manufactured for any specific target
platforms.

>itself though, and many times not even that. It's totally possible to
>make a single card that plugs into everything, but most vendors are too
>lazy.

Businessmen actually obsessed with making money, imagine that?

What you're describing only adds unnecessary cost and wastes space
in a market that is viciously competitive. None of the other potential
platforms require such efforts. They don't waste time being prissy and
pretentious. They do what is required to interface to a given piece of
hardware.

Apparently, a PowerMac is not as up to the challenge as an Atari ST.

Listen you Apple stooge: I said multi-montior video card.

Take the blinders off for a few milliseconds, look through the
driver list of a Win95 machine (standard, Aug95 release, no mods)
and you will find STB's muti-frame buffer card drivers.

[deletia]
>> >

So? Where's the generic T6000, Rage II and CL 5434 drivers?
Where are the specific drivers for the ATI 3D Xpression+TV?
Where can I test a machine that might have a PC PCI video card
in it?

```
    I'm not about to take your word that PnP won't explode into a
    million mac-pieces under that situation.

Nationalism and regionalism is generally redundant.

The label is only regional in a very vague sense and quite possibly may be general to the entire planet. What was specified covers the region from Lisbon to the Urals. Superficially, the term is more of an economic or social distinction.

You're still a petty small minded peasant.

The nature of my character will never change that.

      So, we then end up with a situation where a freeware operating
      system (Linux) has better hardware support than what is sometimes
      the leading microcomputer hardware vendor.

      This is especially strange considering that the Mac userbase is
      estimated to be at least 20 times larger (than linux).

That kinda makes it wasteful for anyone else, now doesn't it.
That also reduces it to 'Mac' hardware, reducing significantly
the usefullness of a common bus standard.

>
>Anyone who has used both machines knows that the Macs multi-monitor

>support is faaaaaaar superior to windows. <period>

BETTER was never the issue. Some clueless MacVocate attempted to claim that it was impossible. Then other MacVocates attempted to backpedal the assertion to be the level of OS support.

BETTER is also vague and subjective.

>
>With a Mac you can plug in multiple different off-the-shelf monitor

>only work one app at a time. Some cards support multiple monitors of

QUIT SPREADING LIES!

This is the DOS way of doing it. DOS has been fairly dead except for gameplay for quite some time now. PC OSes provide virtual devices like any other real OS.

>the same resolution... but the system doesn't know shit about it. (can
>you say cheesy hack?!)

The system doesn't need to know shit about it. All it needs is a way to interface to the screen. On a well abstracted OS, the underlying hardware and configuration of same should be totally transparent.

>
>The Mac was is far superior. <period> MS is lazy, and implemented a
>bad (limiting) design.... and users pay the price.

Actually, filling up all of your card slots, which tend to be limited on a mac to begin with, is rather limiting. In this respect, the PC solution is acutally better. Sure it is a bit lazy. However, a lazy solution is likely to be less complex. A complex solution will be easier to implement and to debug.

Somehow this tactic is horrendous on the PC but good practice on a Mac. MacVocate hypocrisy in action once again...

With limited card expansion space and the price of larger monitors (30"+) coming down. The usefullness of such a general solution diminishes. A significant number of macs would meet or exceed their expansion capacity doing it the 'Mac Way'. PC's would not.

>Nope... people add by making their cards compliant with certain system
>restrictions... just like windoze. There are often FEWER restrictions
>on the Macs than on the PC's. So where is the cost?

Start naming specifics. The only PC restrictions are the bus interface.
Even there, one usually has 2 or 3 options instead of just one. The
card would also need to be VGA compliant but, that is a very limited
specification. Otherwise, MacVocates would have nothing to hark upon.

>
>Apple designed their stuff better... it took longer up front, and more

>>   That should be well understood and freely admitted.
>Anything
>>   else is pure fraud.
>
>Superset? No... Win95 is a cheap hack that is meant to make up for a
>bad initial design (or lack of an initial design)...

Yes. Superset. Win95 has the liability of having to make up for
SOMEONE ELSES bad initial design. MacOS has no such hinderance.
That it succeeds in the absence of handicap is much like a person
with healthy legs outrunning someone with nothing but stubs and
then bragging about it afterwards.

>
>The Mac is well designed, with versitility in mind.
>
>Call Mac PnP a superset of Win95 PnPray is like calling a BMW a

SUBset. You're blathering.

>superset of a Model-T (with electronic ignition and after-market
>air-conditioning bolted on). Sure they both have wheels and a motor-
>but one is designed far superior than the other.

However, that is not the case at all. There is really very little
hardware difference between the two machines. You GROSSLY overstate
their differences. Most of the differences are in your mind. The
rest are primarily a matter of software.

Typical MacVocate pomposity.

>
>>   If anything: Win95 plug & play attempts to be a superset
>of
>>   the Mac's.
>
>It may try... but it falls far short of success.
>
>Mac PnP works.

It gives a man no bragging rights to outrun a man with a ball and chain.

It is MacOS in the subject line after all.
That it succeeds is more a matter of lowering the bar in its favor.

Like what? Without specifics, you're just blathering. Also,
if it is an intermittent problem, you might want to check
the hardware in question.

>and how they would work when they introduced the nubus. As for the
>rest of the PCI stuff, remember how backward the i86 system is.

Oddly enough, despite this backwardsness, Apple still adopted it.
It would be nice if someone could ordain an entirely new architecture
but, the PC market isn't that centralized. There is no 'Big Brother'.
The last PC vendor that tried it, got laughed at (MCA).

>
>It is amazing that any cards work. Apple may not be at the head of the

Odd that I have yet to have such problems...

Drivers for the STB 2 & 4 framebuffer cards are right there for anyone to see in the Win95 drivers list.

The rest would be cards that would also require a driver to work with the Mac assuming that such a driver even existed.

So, what chipsets were those again? S3? CL5428? CL5434? T6000? Rage II?

Nevermind that all of these work fine and require no drivers at all in 'Mac Plug-n-Play mode'.

No, the Mac just specifies quite a bit more. There is no flexibility
there. It is a straight jacket really.

The above quoted macVocate text is a perfect example of MacNewSpeak.

BTW-onboard drivers nullify any point in using a multiplatform bus.

Such responses are the last attempts of feeble minds.
The Mac platform imposes certain restrictions based upon the
engineering models that it is built upon. Glossing over such
issues with ANY device is blatant fraud.

>
>> Users should know exactly what they're getting. They should

They also might curtail sales. Conventionally, such information
hiding is refered to as fraud.

Apparently, you don't think that the Mac would look very good in
the face of full disclosure. Otherwise, you should be more forth-
coming.

     What will this do to the current price structure?
     NextStep currently sells for $800-$4200.

Or, rather, that that machine uses what hardware it does have more efficiently. The entire point of multi-tasking systems is to maximize concurrency on hardware that supports such things. That mix appears to flex most of his parallel operable components at once.

It shouldn't slow down user responsiveness. It shouldn't starve processes either. Some may get low priority but, that's the entire point of batch processes to begin with.

If we wanted them given maximum priority, we'd nice them or bring them into the foreground.

The only things that should flex the CPU is the renderings.
Those can proceed at sub-optimal speed because they're batch jobs.
The rest should put no more than %10 load on even a 486/100.

Actually, according to the company man, Quickdraw is just another
version of OpenGL (or DirecX). Since my 2D only PC card works just
fine with OpenGL, a VGA or EGA card should do just as easily...

Mac PnP still turns into VGA++.

So? What will QuickDraw do with a T6000 card? Blow Bloody Chunks?

```

> >regionalism. Neither contributes to your logos.
>
>   Nationalism and regionalism is generally redundant.

Um, shouldn't that be "Nationalism and Regionalism 'are' generally redundant?" Regardless, that is an entirely untrue point. An individual purporting that, say, the NAFTA economic system is superior to the EEC is engaging in regionalism. A Canadian extolling his country as superior to all others is engaging in nationalism. Neither is mutually exclusive, but this does not equate them.

>
>   The label is only regional in a very vague sense and quite possibly
>   may be general to the entire planet.

Perhaps, but your labeling him as stupid or unable to comprehend certain societal and economic conditions due to his European origin is hardly non-regional or "vague." It is like saying that an American cannot understand socialism due to his capitalist nation's system. This is a fallacy of 'capital' order.

>What was specified covers the
>   region from Lisbon to the Urals. Superficially, the term is more of
>   an economic or social distinction.

Exactly, and has little (if any) validity as a judgment criteria for qualification, or lack thereof. If one was, for example, to describe himself as a chimney sweep with a second grade education, no computer knowledge, residing in London's Southwark borough, this would be an adaquate criterion to suggest that he may not be knowledgeable about Macintosh API programming theory. Suggesting, however, that a "European" has no concept of such economic and technical matters is sheer fallacy.

>
>   You're still a petty small minded peasant.
>

This is the fallacy of the "red herring," in which a desperate/losing debater slanders/insults the opposing party in an attempt to escape the irrefutable logical points and provoke an emotional outburst in the recipient. When successful, the red herring allows the user to switch to a topic more suited to his limited understanding. Unfortunately, yours did not succeed.

>   The nature of my character will never change that.

An equally dubious fallacy, referred to as the "self-immolation" (self-burning) fallacy. This fallacy positions an attack upon a logical fallacy by an opponent as an attack upon the individual or a key component of an individual (such as character). This is designed to garner sympathy or lessen severity of logical scrutiny. Again, your tactic was not successful.

Usually, sticking to the topic is the most effective means of
discussion, no?

By the way, I just installed an IMC 1724PDS graphics card for my 6300.

I unscrewed the back panel, and then I pulled out the tray containing the mother board completely out of the machine.

The board has pin edges right across it's back and connects to the peripherals with a very long connector deep in the back of the machine. There are absolutely no ribbons whatsover.

I punched out the preset holes for the port opening, and I carefully inserted the card over the PDS slot. The card looks more like a daughterboard, and there are chips galore in the top and the bottom. I gently pushed down the card, and the design of the PDS connector is strong enough to hold the card in place once it's fully inserted without need to screw it to the frame. I pressed a tiny red reset button on the motherboard with the screwdriver.

I placed the motherboard back to the rails, and slid it inside the machine. The backedge connectors made a slick, firm connection. I put the two screws in, tucked in the small metal handle used to pull the board out, snapped the plastic cover. Then I reconnected the Mac to the power, monitor, modem and printer.

I boot and wallah. Checking my Monitor Control Panel, the new resolutions are all automatically there.

I inserted my 1724 diskette, and I dragged and dropped the 1724 CDEV into the Control Panels. By default, Quickdraw Acceleration is already marked and enabled. Any changes on the 1724 Control Panel is immedietely active the moment the CDEV is closed---no need to reboot. You only need the control panel to enable or disable Quickdraw acceleration---on the fly, as well as to reassign the keystrokes for pan and zooming. All immedietely active the moment the CDEV is closed.

And without having to reboot again, I am already panning and zooming in a virtual deskop across different resolution modes and color depths that are being set on the fly.

Totally painless and plug and play.

I don't have to hunt and browse for some F*CKNG.DLL, SETUP or ST*PD.INF information file in "D:\WIN95" from the Display applet, after I have to pick a card from some long list or run a procedure that lets me wait for several long minutes to detect what card is that, which can happen unless you stop Windows 95 from doing it. Then after this trouble and you have all the nice graphics cards utlities set and all do all the tricks and stuff, installing DirectX would render all these utilities Completely Useless, and if you want these utilities to work again, you have to uninstall DirectX or reinstall the drivers. And for all that trouble, you end up with an unstable system because the end result is a spagetti mess of different DLLs from different drivers. Guess what, I finally had to completely reinstall Windows because it needs to be cleaned up anyway, and then only to discover that in SAFE mode, which is the only way Windows 95 would boot up when it's all screwed up, that it won't RECOGNIZE THE CD ROM drive where my Windows 95 CD ROM is waiting. Worst, I can't shut down to pure DOS to start my DOS CD ROM driver.   When I finally did so, Windows 95 SETUP won't even format or delete the old directory, so the reinstall procedure stopped somewhere. Jeez---And after spending many minutes in my file cabinet looking for that paper with my license number that you must enter in one of the many annoying questions in the Windows 95 install procedure. (Somewhere I was so closed to tears, had the strong temptation to break my CD ROM in half, and left a big crack in my PC casing after I punched it.) It's one disaster leading to another, and I finally rebooted my OS/2 Warp partition and from there, wiped out all Windows directories and assorted junk as clean as possible and run disk utilities to assure partition integrity before I rebooted again to my FAT partition and tried the install again. (My OS/2 partition sees my Windows 95 partition but not the other way around.)

"20th anniversary" ... "Mac".

Has a timewarp suddenly occurred, and we are now in 2004? (checks watch).
Nope. If the Mac was relased in 1984, and it was "designed" during 1983
as a replacement for the commercial failure known as the Lisa, then it is
only 13 years old.

Perhaps you are referring to the 20th anniversary of the 8-bit Apple. But
that was 1996. (The Apple][was a 1976 release)

> I want one but can afford the reported $9000 price tag. However, I am

> excepting donations.. So send your unwanted pocket change to me...:-)

"excepting donations".
Transalation: "excluding donations".
Meaning: Dont send any.

The in-context word our "friend" probably meant to use was "accepting"

(This is an error that any good librarian [as I am led to believe our
"friend" here is] would pick up in a cursory reading of the above quoted
two lines of text)

No, Toad is not the ONLY company. Computer Direct is pretty well
exclusively devoted to TOS and MagiC platforms. Toad is hyping their PCs
(with Gemulator built in) and their Internet service provider business.
They still sell Atari stuff, and provide support, but appear to be
winding down their involvement in the world of TOS computing. Computer
Direct, on the other hand, will only sell you a Mac or Mac Clone if you
REALLY insist, and steadfastly refuse to have anything whatsoever to do
with PCs. Check them out at http://compdirect.com. They are doing some
really amazing stuff.

blink whaaa?

You are, in fact, aware that Quickdraw was around maybe ten _years_ before anybody was thinking about calling anything DirectX? Very strange behavior.

This has been the situation since probably the Mac II in '87, definitely
since 32-bit Quickdraw in '89

What is so hard for you to understand? Any PCI card will work with the appropriate driver either on the card itself or installed by the user as an extension/control panel. This is the same as on any other OS.

I didn't even bother to reply to that joker who claimed that his 10x CD-ROM drive requires a special driver for Windows 95. He just made it up. For all we know, he could be a Macloser in disguise. I never knew there's a 10x CD-ROM drive that's neither EIDE (ATAPI) or SCSI!

Don't worry, IBM is the greatest computer company in the world (maybe
even universe). I think OS/2 depends on 3 things:
a) IBM's research: which is exceptionally good and keeps producing new
products (I expect good voice output in 2 years maximum).
b) IBM's money: which they use for very good purposes (buying Lotus,
getting NS/2).
c) Lack of competition: Microsoft products do not stand a change, and
until Apple get the NeXTOS done, they also are no challenge.

Note that Java, NC, etc. is part of the research (Sun works with IBM
so well, I think they should join forces or something).

Depends on the video card / driver combo.

Anyone here seen the way Be does it? Pretty awesome.

>such when the time comes.

I need to correct you in that you may TRY to sell your Atari for any price you
wish to ask for, but finding a sucker to pay it is another matter altogether.
I can go to local electronic discount resellers(USED) and find 1040ST computers

stacked in bins for $30 to $50 each depending on condition. If you purchased your computer thinking it would hold its value like a fine collectable, you are VERY mistaken. Computers lose their value almost as fast as the ice-cream cone you purchase from a street-side vendor on a HOT summer day. If I constantly thought about what I have paid for hardware and what its worth now. I would NEVER buy another computer again...

<<
Does NT support multiple monitors? Or does a special video card and
driver set? Can I take my NT workstation that I'm typing this on, and
add any graphics card I want and have multiple monitors? If NT
supports multiple monitors, then I shouldn't have any problems doing
it should I? If you answer that I need to buy a special video card,
then I don't think NT supports this...the specialized video card does.
>>

NT supports it if your driver supports it, some video drivers need to use fixed addresses of hardware, so you could not place two cards working simultaneously, some new PCI p&P video cards allow dynamic reconfiguration for hardware, so you could use two standard cards simultaneously, The trouble is on the Hard and on the Drivers, Not on the OS, specially when the OS likes to controls so absolutely the hardware as NT does.

Hi,

An ICD Link II would be the "cable" you need. It is more than just
a cable though. It is a SCSI host adaptor as well. It allows your
Atari's ACSI port to talk to the hard drive's imbedded SCSI interface.

It should be noted that some models of SCSI drives are not useable
with the Link II. If you can send me the info on the drive, I can help
determine the suitability for this solution.

As far as driver software goes, the Link II comes with software which is
not bad, pretty good actually. The best software to use in my opinion
is HD Driver.

If you have any further questions or need help determining whether or not this particular drive is useable, drop me a line!

All the best,
Chris @ Computer Direct

>What is so hard for you to understand?  Any PCI card will work with the

    Conflicting statements are hard to understand. You MacVocates can't
    even get your minor, user level, technical details straight and you
    seriously expect me to take your word on a matter of QA? Take a reality
    pill.

    Some of you attempt to claim that the core of Mac Plug & Play is
    a matter of restrictive specification. If this is the case, it
    severly cheapens past Mac success and casts serious doubt onto
    whether or not it can succeed in an enviroment as complex as what
    PC components provide.

>appropriate driver either on the card itself or installed by the user as an
>extension/control panel.  This is the same as on any other OS.

    However, MacVocates are seldom willing to admit that it would be that
    simple on any other OS. If the Mac is emulating Win behaivor, and
    rather new at it, it would not be entirely unexpected that the Mac
```

would be emulating that behaivor 'entirely'.

Regardless, I request verification: a not unreasonable request for any one with a mind of their own.

Were you aware that you are concentrating upon a parenthetical footnote while at the same time ignoring the prime focus of my statement?

One might get the impression that you're unwilling to address the technical details of my statement. They might prove embarassing for you. Instead, you rant on about red herring timing details centered around a minor footnote. No one cares about ancient history. We are not comparing Win85 to Mac85. It's time to stop living in the past.

You did not address the statement. How is QuickDraw not an application level API layered over a standardized dumb frame buffer driver? Age does not equal superiority; features do.

MacVocates are having a hard time coming up with usable non-esoteric features that would make up for it's [Mac] position in the marketplace.

They're all 'special video cards' and 'special driver sets'.

Either way, even according to the apple company man, you're going to need drivers buried down in the operating system to use any video card on either platform. This is, if you want to use the full capacities of the card you've likely spent a greater amount of money on for the Mac.

Either you pay more for a card from a vendor that's macbending over forward for you (increasing fab cost) or you're using only the very basic functions of the card (and wasting that expensive card) or installing a driver yourself (like everyone else).

Since the Mac isn't very capable of just plugging in any $40 PCI video card, the Mac concept of 'plugging in any card' is quite a bit limited.

In this respect, plugging in yet another overpriced Mac board or an overpriced speciality PC card don't leave much net difference.

However, the PC will be left with more expansion room afterwards.

Try reading your atari disks on a Win95 machine. Microsoft finally introduced an Atari-esqe extended disk format for it. I suddenly

found that my Atari disks were readable after all this time. PC
hardware should have no trouble with Atari disks really. I'm not
sure what the problem was before...

Or, if that doesn't work: use a null modem cable and the corresponding
terminal emulation software. There are also more advanced serial port
xfer option but, I have no experience with them (ghostlink?).

Most cards do, but it's not required. The driver could be on the disk, but then the video card would not be used until the OS was booted.

It is pretty equivalent to a ROM BIOS. And, like a ROM BIOS, it is quite neccessary. OpenFirmware is an open standard for interfacing OS's and system ROMs to a system's onbaord and plug in hardware that is required for booting. At a minimum this includes a bus interface like SCSI or IDE and a mass storage device or a network connection like ethernet (for net booting). If you want to be able to present a boot OS selection to the user, OF driver code would also need to be provided for a keyboard and monitor.

As the name implies, Open Firmware is designed to be implemented on many different platforms including Sparc, x86, PowerPC, etc. It is used by Apple and Sun and is part of the CHRP standard. Open Firmware drivers are written in Forth and are not processor specific; the drivers are run by an interpreter in the system ROM (kind of like a Java for booting). The BIOS design is pretty x86 specific by using the x86 interrupt vector mechanisms.

If a plug in card (like a PCI SCSI card) contains an OF driver, any system that implements OF may boot off of a hard drive hooked to the card. Thus, the SCSI vendor can implement one PCI card with one driver in its ROM and a user can buy this card for his Mac, Sun Workstation (they're working on PCI versions), or CHRP box, plug in his boot drive and be able to boot through the card. Once the OS is loaded, a better, processor/OS specific driver may be loaded for the card to get better performance. OF is mainly intended just to get things booted. Sun uses the trademarked name OpenBoot which is more descriptive for what it does.

Conceivably, everyone could have standardized on BIOS and written x86 interpreters in their system ROMs so they could run BIOS drivers on all of the PC cards. Forth (or some other interpreted language) seems a little more open.

As diplomatic as I try to be, I'm still called an "Apple stooge." I'm merely trying to point out the differences between Mac and Windows support for multi-monitors (either multi-monitor card support or multi-card monitor support). Mac can support multiple monitors and Windows can support multiple monitors. How they accomplish that is different.

Some people on this thread have talked about multi-monitor card support and some have mentioned multi-card monitor support. I have only tried to describe how each is supported by Mac and Windows.

The idea of dumb, bit-mapped frame buffers have been around a long time. I don't know when OpenGL was developed, but I know the Commodore 64, Apple II, and many other computers of those days had some form of bit-mapped frame buffer. A lot of games in those days used text mode as a form of bit-mapped (albeit with rather large pixels) frame buffer. I'm not claiming that Quickdraw's use of bit mapped frame buffers was revolutionary; it was actually a pretty well established technique at the time.

>     in it?
>

  I've worked with ATI, Matrox, and Chips and Technologies to get their
PCI video cards working on the Mac.  The hardware was the same as they
used in the PCs.  The only thing that made them PC or Mac PCI cards were
the drivers.  One of the reasons Apple switched to PCI was so that 3rd
parties could implement one piece of hardware and just have to do extra
software for the Mac.  Sometimes, even this effort is too much, though.
This could be the case for T6000, Rage II and CL 5434.

>     I'm not about to take your word that PnP won't explode into a

  PnP shouldn't explode into a million mac-hardware-pieces.  Just a
million (well, only as many cards are out) mac-driver-pieces.

Your statement (well, question really) is correct. QuickDraw is an application level API layered over a programming interface with hooks for graphics accelerators layered over a standard driver interface to control a dumb frame buffer. Many of the bit blitting and other drawing routines call through installable procs to do their work. QuickDraw installs procs that do the drawing in software. Third party drivers may install procs that do the drawing using graphics acceleration hardware. I'm not trying to say that Quickdraw is superior in this respect, but rather I'm anwering your question.

> MacVocates are having a hard time coming up with usable non-esoteric features that would make up for it's [Mac] position in the marketplace.

I wouldn't argue that any of Quickdraw's features are superior to Windows. As for graphics, Quickdraw and the Windows architecture are mostly capable of the same things. The value any user puts on various features or a platform's position in the marketplace is highly subjective. Most users probably don't care that the Mac or Windows can support some configurations with more than one monitor. The statistics I've seen place the number of Mac users with more than one monitor at less than 5%. Mostly video professionals and software developers take advantage of multiple monitor support for the Mac or Windows.

You are confusing yourself. We say that plug-n-play works well on the Mac because there is better integration of hardware and software. YOU come back with a huge leap in logic that says somehow this 'integration' bespeaks restrictive technology. That is your term, not ours. You have assumed that the spec is restrictive. it isn't. Mac video, for instance, Apple provides SYSTEM LEVEL support to a frame buffer which will, without any additional software, support any size monitor at any bit depth from 16 colors to millions of colors, at any resolution supported by both the monitor and hardware, and limited only by the VRAM available in the accompanying video hardware. And it will do so for as many video hardware boards as you like. Want to run 4-21" monitors at 24 bit as 1 huge contiguous screem? Just install three video boards and put 4 megs of VRAM in the Mac's on-board video circuitry. The SYSTEM will manage those monitors just fine with no additional software to do so. Try that with a PC (without "special drivers"). Now, you tell me, where is the restriction? Any acceleration that the hardware supports is provided by an extension supplied by the hardware manufacturer. Apple has its own accelerator for the on-board video and third parties supply it for their boards. If you install 3 identical boards only one accelerator extension is required for all of them.

I just installed an Apple 'QuickDraw 3D' accelerator board in my Power Computing PowerCenter machine. I inserted it in an empty PCI slot, restarted the computer, inserted the CD that came with the board and ran the installer. In seconds, the installer had installed the necessary software on my machine and restarted. The installer is even smart enough to know that the version of QD3D that I had installed was a later version than the one on the CD and it did NOT try to install the earlier version over the later the way many PC installers seem to do. It worked perfectly the first time, no 'autoconfigure' tasks to run, no bios settings to change, it just works (BTW RayDream Studio now renders 3D so fast that I can hardly believe it. Would you believe a 600 x 400 pixel 24 bit 3D image at 600 DPI in 12 minutes?). This is hardly "restrictive technology"

There's one problem with your above assertion. How can the Mac
be "emulating Win behaivor" when the Mac had it long before
anyone ever heard of Windows (try circa 1985)?

OpenFirmware is part of the latest PCI specification. Cards that conform to that spec will work with Macs.

OpenFirmware is a bit different from a more traditional ROM BIOS in that it is not dependant on the machine it is plugged into. It allows PowerMacs with PCI and PCs with PCI or Alphas with PCI etc. to access the same cards with 'plug and play'. It is a way for the computer to communicate and setup the card without proprietary hardware specifications that are dependant on a particular machine's architecture.

Intel is part of the consortium that decides on the PCI spec. PCI is an open standard, and Apple impliments PCI in it's PowerMacs.

Are they plug and play too?

>   platforms.

I don't think he was correct here.

OF does not target any specific platform. OpenFirmware is independant of the machine it is running on. It's vaguely like Java for expansion cards. It allows different machines with different architectures to access the same cards with out specific support for that platform on the card.

>   Apparently, a PowerMac is not as up to the challenge as an Atari ST.

I don't thing he was correct. PCI cards that fully impliment OpenFirmware do not care what machine they are running on as long as the PCI bus of that machine conforms to revision 2.1 of the PCI spec.

Why don't you explain exactly how much more the Mac specifies?

>     The above quoted macVocate text is a perfect example of MacNewSpeak.
>
>     BTW-onboard drivers nullify any point in using a multiplatform bus.

It is supposed to be a machine neutral language for initial communication
with and setup of the card. Drivers are usually there to get the video
acceleration (at least on Macs... I don't know if a video card will
display anything on PCs without the driver; I have no experience with such).

My word comes from experience as a Mac user and a programmer and was also verified on this newsgroup in this thread by a programmer from Apple. I don't know where the original poster got his information from. By the way, what makes you think that I'm a "MacVocate" just because I am correcting your obviously incorrect frothing? (Hint: Look at the headers and see what newsreader I'm using).

I never claimed otherwise. The Mac's video driver architecture/ API is more robust than the Windows driver/API architecture. You aren't limited to just a view compatible cards for multi monitor support. SCSI is still more problematic even with Win '95 than it is on the Mac.

Hell, go to Apple's web site and find the driver documentation.

Yes.

There are many video cards that can do this, and some even support two monitors with one card.

Try plugging in two PCI Matrox Millenium cards. NT will allow you to set up a panning display with both monitors. Real neat.

Nonsense. QuickDraw is an API (like OpenGL). APIs are nothing new. Apple
did not swipe the idea from OpenGL.

PCs use the same principles to accelerate some video operations as Macs.

Some of the functions in QuickDraw and in the Windows GDI can be done
with the custom chips on the accelerator card rather than having the CPU
do it. This is precisely how PCs and Macs get video acceleration when
adding a graphics card.

I'm surprised that you're even making this an issue.

If the driver does not exist for the Mac, then the card won't do anything useful, but the sound card or the CD-ROM won't stop working when you plug it in (as could sometimes be the case with PCs before PnP conforming hardware from what I hear).

Umm.... no, I don't think I believe that one.

My roommate has a PC that has one PCI slot left. He has added nothing to his system since recieving it. That was the way it came.

PCI Macs OTOH have at least 3 free PCI slots. Those with 6 PCI slots don't come with on-board video and have one slot taken by the graphics card.

What are you talking about?

Which "PC solution" is actually better/lazy?

<snip>
> >Apple designed their stuff better... it took longer up front, and more

What? For not implimenting a useful feature that needs special solutions to get around?

Superset, subset... both would be the wrong choice of words in this situation.

Neither is a set of the other. Arguing super/sub sets is totally irrelevant in this case.

Arguing that Microsoft's feat of getting around a hardware design limitation was rather impressive and that Apple had no such initial design limitation to overcome might be more reasonable. Arguing super/subsets of anything is not.

We should pity the man with the ball and chain. Wait, no... we should laugh at the man with the ball and chain for his foolishness because he could have removed it long ago, but had chosen not to. Now, rather than throw it away, he simply carts it around.

'Sure I could take it off, but look at the pretty cart I can tow it around in now! Isn't it nice?'
-The Man With the Ball and Chain

>   It is MacOS in the subject line after all.
>   That it succeeds is more a matter of lowering the bar in its favor.

Yeah... PCs are really virtuous. The PC architecture makes it harder to do the same things other systems can do because these other systems were designed better. That sounds good.

How special are they? The Mac version of the Matrox, ATI, Diamond, Number Nine cards as well as the SCSI cards look very much the same or identical to the PC versions.

Yeah right. The list price of a 4Mb Matrox is the same for a PC and the Mac.

>

Nonsense. I just installed a $250 video card on my Mac, and every function
is immedietely available. The only software needed is to turn the card features
off and on---without rebooting too.

>   Since the Mac isn't very capable of just plugging in any $40 PCI video

>   overpriced speciality PC card don't leave much net difference.

I see one Mac PCI graphics card (IMC brand) being advertised for I think $149.
Does that sound overpriced to you?

This sounds like a contradiction to me. If it is possible to implement sockets on cooperative TOS, how is it "utterly impossible" to implement sockets on cooperative MacOS?

And I seem to recall seeing sockets running just fine on good ol' cooperative Windows 3.1...

>And ? Will MAC OS8 be pre-emtive and have BSD-socket support like so many

If MacOS 8 was still going to be done, yes, it would be preemptive, and no, it would *not* have BSD-sockets support. It would have Open Transport. OT is based on several standards which originated on UNIX variants.

Believe it or not, BSD sockets are not the ONLY thing under the sun.

Judging from your tagline, your two primary operating systems are MagiC and Linux. Interestingly, you would be better off with a PowerMac than a Falcon, because you can run both of those OS's on one. Trust me, literally any PowerPC will leave a 40 MHz 68030 in the dust. You just have to be careful that the PowerMac you get is compatible with one of the two PowerMac Linux releases (MkLinux or the semi-unnamed PCI Mac Linux, sometimes called pci-linux or linux-pmac).

I don't trust BYTEmarks. They appear to completely fail to test memory subsystem performance, which is a very important thing to measure in the modern world.

>Remember, also, that 250MHz 604e chips are shipping and the fastest Pentium
>Pro is only 200MHz.

I wouldn't be so confident throwing a word like "shipping" around. The fact that Power Computing has announced dual 604e-250 systems doesn't mean you can actually buy one yet. I had a bad enough time trying to get hold of a 200 MHz 604e card for my 7500; I ended up canceling the order after a long wait and bought a 604/120 card for $99, which I clock chipped to 150 MHz. I shudder to think how hard it must be to get the 250 MHz chips.

SPEC results are almost always reported by the company that makes the chips. Didn't you notice that the PowerPC numbers were from www.ibm.com?

>Let's see the numbers for DayStar, and Apple high-performance computers
>and compare again. And compare processors to processors, not IBM
>computers to Intel processors.

Intel uses Intel computers, based on a hot Intel motherboard. It is safe to assume IBM does the same (the numbers for the 225 MHz 604e IBM puts out are for 1MB L2 cache and 64 MB of SDRAM on a memory bus running at 75 MHz).

It is difficult to get numbers for DayStar, or any PowerMac. SPEC runs only under UNIX. Right now, the only UNIX that runs on PowerMacs is Linux, and neither port (the monolithic kernel port or MkLinux) has been well optimized. (MkLinux in particular appears to be pretty slow.)

Even with an optimized UNIX, I predict that you wouldn't like the numbers. Based on my benchmarking of my 7500 with John McCalpin's STREAM benchmark, which tests memory bandwidth, PowerMacs have fairly anemic memory throughput compared to common Pentium boards. As with any real world benchmark, the programs in SPEC test memory bandwidth, though not nearly as single-mindedly as STREAM.

Apple really needs to push the system bus speed well above 50 MHz, and
start using pipeline burst cache SRAM instead of flow-through burst to
take advantage of the high bus clock.

> The difference is that the Mac OS has a published driver, so the crad vendor doesn't have to provide one. Acceleration (3D at least) is provided in a plug-in system so you only write drivers FOR those functions. These can them be placed on the card for OpenFirmware to load into the Mac for you.

Card vendors do have to provide drivers for video cards on the Mac. The driver is used to set the resolution, refresh rate, bit depth, get the base address of the frame buffer and other things.

From what I understand of the Windows driver model, a Windows video driver must also provide functionality for setting pixels (I think this is the bare minimum, but would give you very limited performance), drawing lines, doing blits, etc. A graphics card vendor could get away with just providing VGA functionality and could then rely upon a VGA driver provided in Windows. This too would give pretty limited performance. Since most people are used to the speeds provided by graphics acceleraters, a basic VGA card wouldn't sell too well these days. The MacOS could provide a VGA driver out of the box, but there probably wouldn't be enough demand to warrant the effort.

On the Mac, if you want to enable hardware graphics acceleration, your driver would also need to provide functionality for drawing lines, doing blits, etc. as well.

> I don't think he was correct here.

I was right, JEDI read the sentance incorrectly. I was noting that any

PCI card on any platform needs a driver for that platform. He then turned around and thought this implied that all OF cards need to have _all_ drivers on it. That's not what I was saying at all.

> I don't thing he was correct. PCI cards that fully impliment OpenFirmware do
> not care what machine they are running on as long as the PCI bus of that

There is no prime focus in your statement, unless it's that OpenGL runs on 2D card. Gee, stop the presses. The same is just as true on the Mac which runs both QD3D and (now) OpenGL as well, with or without 3D cards.

>   One might get the impression that you're unwilling to address the

I don't know if anybody here can help but if there is anybody familiar
with the Atari Portfolio parallel port file Xfer, please e-mail me at
wx191@freenet.victoria.bc.ca

I have lost the manual for the Xfer software and am having problems
trying to get files across. These may be very simple problems with easy

solutions but I've never used the parallel interface for anything but printing so I am at a loss here.

Thanx.
mda.

        This is not remarkable. The same is true of ISA in practice.

You should. All PCs are limited to your rather miniscule experience.

>
>My roommate has a PC that has one PCI slot left. He has added nothing to

PC's aren't limited to PCI slots. They are also not limited to one vendor's view of how a system should be.

>
>PCI Macs OTOH have at least 3 free PCI slots. Those with 6 PCI slots
>don't come with on-board video and have one slot taken by the graphics

Configurability is a double edged sword & there is nothing limiting what a PC vendor might do to you. However, there's no good reason that his machine didn't have 3 PCI slots free.

He should never have tolerated that system.

```

     a) Buy a new card & monitor
     b) Buy a new card & monitor

     Those two actions sequences are identical.

     The solution is hardly 'special', support is delivered with the OS.
     It's just not done so in a manner identical to somone else's solution.

The argument was never the hardware but, the software. When apple
can manage to port it's OS to an ISA PC and still manage it's
'feats', then MacVocates can prance and brag.

Until then, such behaivor is pure sleaze.

```

Actually, DirectX just lays on top of the device driver. It is unclear if, or how long QuickDraw has had access to a 2D or 3D hardware acceleration interface. Without such a thing, QuickDraw is rather limited. With such a thing, MacOS has to either have a driver api or another iteration of it's VGA++ spec.

How many times by how many different people do you have to here that the
MacOS has had a driver API since the first Mac II rolled off the assembly
line in '87. Hell, even a programmer from Apple responded to this post.

A big dumb frame buffer is still just a dumb frame buffer.
My use of VGA++ was an acknowledgement of the fact that
Apple's version of VGA trumps the PC version. However, it
is still just VGA.

It was also a reference to Orwell that, aparently, no one got.

>And it will do so for as many video hardware boards as you
>like. Want to run 4-21" monitors at 24 bit as 1 huge contiguous
>screem? Just install three video boards and put 4 megs of

>manage those monitors just fine with no additional software

I'd rather just sink the money used to get the 3 extra video
boards into 1 better video card & use the money used in purchasing
4 monitors to just buy one with more screen area.

>to do so. Try that with a PC (without "special drivers").

Unless you want a dumb frame buffer, they're all
"special drivers" on either platform.

>Now, you tell me, where is the restriction? Any acceleration
>that the hardware supports is provided by an extension supplied
>by the hardware manufacturer. Apple has its own accelerator

It's not a 'special driver', its an 'extension'.

More MacVocate hypocrisy in action...

Odd that the vast majority of PC installers (of any kind)
ask when they are about to overwrite a newer version. Although,
installation utilities are the responsibility of developers and
not the OS vendor.

>no 'autoconfigure' tasks to run, no bios settings to change,

Win95/NT have the architectural structures in place to
accomplish what you describe.

Try circa 1981. DOS 1.0 had the same level of PnP as MacOS
did in 1985: VGA++ (CGA).

Now, when MacOS finally got around to supporting a device driver
api is another matter. That has yet to be addressed by anyone.

Actually, PC VGA video cards are plug & play. Most of the problems with multiple video cards stems from that (PnP) specification being too specific.

Now, for non-trivial video functions: both platforms seem equal. Both have to deal with the likes of Diamond and Matrox.

Oh. I'd read it as "20th anniversary Mac" ie the Mac was 20 years old.

My error. (the 4th one this decade)

Then that poster was full of it. Real-world programs exercise the memory
subsystem, so you'd better benchmark it if you want to find out how fast
your computer is going to be.

AFAIK, UMAX hasn't even announced 250 MHz. The piece in MacWorld said 240
for UMAX, and also said that Power Computing announced a dual-250, and
showed a technology demo 300.

Boy are you dense (or stubborn)! No drivers to run as many
monitors as you have PCI slots. On some machines this is
as high as six! No drivers, no drivers, no drivers. Get it?

>

That's right. Its not a driver, it an extension. Take all of your
'drivers' out of your PC and see if you get any video. You won't!
I can ALL of the extensions out of my system and I will still get
video!

I believe that the 240MHz UMAX box uses a 603e chip. I'm talking 604e here.

I believe this statement is incorrect. First, all PC video cards that I'm aware of support the VGA standard. It's not that great but it is there. Second, the two video cards that I've got in the last couple of years have VESA support on the cards firmware (don't know about PCI cards though). I don't recall VESA driver in Windows 3.1 but GEOS has them.

Oh. I'd read it as "20th anniversary Mac" ie the Mac was 20 years old.

However, in my defence, it was posted at 3:50AM, (my ISP timestamped it at
3:56, but their clock is always 6 mins ahead of the real time) and I guess
I was a little less than 100% awake.

My error. (The fourth one this decade). Sorry.

Afterword to my own post: I found out today that SPEC may be less memory
intensive than I thought it was.

Moron. There IS no ISA standard (that's one of the reasons the industry has leapt into the arms of PCI wholeheartedly -- it's actually well defined, as opposed to just sort of existing in ISA's case). ISA cards cannot be autoconfigured. ISA cards assume x86 I/O space addressing, and PC/AT style DMA and interrupts. ISA is, with very few exceptions, limited to the PC.

What people have been trying to pound into your head is that OF lets you write a OF driver in Fortran for your PCI card, burn the CPU-independent FCode into the card's ROM, and then the card automatically works on any machine with a PCI bus and OF. It doesn't matter what the CPU is, even. You can plug the card into a PowerMac or a Sun; it'll work in either machine, without even knowing or caring that the CPU is a PowerPC in one and a SPARC in the other. If you want, you can supply as many machine-specific drivers in the ROM as you like, or let the OS of the machine in question use the OF identification facilities to automatically figure out what driver, if any, should be loaded from disk.

You cannot do that with ISA.

You can't buy a single monitor with as much screen area (area = pixels) as four 21" monitors. AFAIK, the best you can do is somewhere around 4000 pixels horizontally, and that kind of monitor would put a much huger dent in your pocketbook than four conventional 21" monitors capable of

1600x1200.

Actually Mac extension conflicts are not all that common. I know people who have had Macs for years and never had one. The problem arises when someone uses a lot of shareware extensions and control panels (which I will cal by their old name "inits" because its easier to type) Apple has a strict programming protocol for inits, that if followed, should never give trouble. Unfortunately, the temptation to gain some advantage by circumventing those protocols is often great, and then you end up with problems. Some third-party mfgs succumb to this temptation as well. NOW software makes a set of utilities that at one time were shareware. Most "Power" Mac users wouldn't be without some of them (Now Startup Manager, Now Menus. Now Wysiwyg, and Super Boomerang being the most popular) because of their humbel beginings as shareware, this suite of extensions can be troublesome. They used to cause problems constantly. The latest versions (6.5) are nuch more stable than they used to be, but it is still possible for one of their pref files to get corrupted, then watch out. Since it is impossible for any of us to know what a person who comes here for help is running, yes, we always suggest that he start the search for his problem with all extensions turned off. That does not mean, however, that an extension conflict is ALWAYS the culprit as you suggest in your above comments. Various conflict resolvers, are, on the Mac side, a lot like un-installers on the PC. Mot absolutely necessary, but nice to have around when you need them. BTW, those who never install ANY third part inits on their Macs, never have init conflicts. The Apple supplied system inits do not (as a general rule) conflict with one another because Apple requires that they are written to spec. Then the new ones are tested in house with all other Apple inits to make sure.

Whoa! Back-up here. I wasn't aware that Iomega made video cards! All
we are talking about here IS VIDEO DISPLAY. And I have a new ATI
PCI video card in my Power Computing PowerCenter, it came with no
software, no drivers. Plug it in, turn on the computer and it works
at any resolution and any screen size supported by 4 megs of VRAM.

Of course, some hardware additions need inits to work, otherwise the computer has no way of knowing the stuff is there or what its supposed to do. No one is trying to deny that. Its just that on the Mac, monitor support ain't one of them!

>

They do not exist, Sang, BECAUSE THEY ARE NOT REQUIRED! Some video boards, as I've pointed out before, may do special things (like acceleration which can be turned on or off, or the ability to zoom in and out of the screen by using some macro commands), these, of course require an extenion or control panel to enable these features, but leave the control panel OUT and the video board still works, still allows you to switch resolutions and bit depths on the fly. Once again, VIDEO drivers do not exist for Mac video boards, PCI, Nu-bus, or PDS, because they aren't needed!!!!! I don't see how I can get any clearer than that.

No, since PC:s doesn't have SMB networking in BIOS they need to load
that support from a local disk.

BTW: NT's loader doesn't care about C:, D: etc either, it uses drive
and partition numbers to address the correct partition on the correct
drive. (Check BOOT.INI on a bootable NT partition)

Not internally scriptable. Scriptable across applications.

You can boot Win '95 from a Zip Drive, CD-ROM drive?

> >I am amazed that Windows (NT, 95, CE) still have lame alias architectures
>
> Alias?

They are called shortcuts in Windows. If you make a shortcut in Windows and then move or rename the file. Windows has a hard time finding it. The Mac can track the original file no matter what you do to it. On a related note, create a file in Word and then go out to the Explorer, assuming you are allowed to, now move and rename the file and go back into Word and see what happens. I did this on the Mac without even thinking. The application knew the file had moved and had been renamed and was still able to save the file in the new location and with the new name.

Because Mac users often have no fear of changing their system around (unlike PC people)... and Macs are still computers. They CAN get themselves in trouble... it just takes 100 times more work - or for them to start doing things that they can't do on a windoze machine to begin with.

> On the other hand, I've never even seen a driver "conflict" on a
> Wintel machine. Please elaborate.

Try any conflict with Autoexec.bat, Config.sys, BIOS not recognizing a device, or devices that aren't recognized or don't work, etc., etc...

>
>   At least some of the microsoft OSes have a HAL.

Sure... and those OS's (WinNT) don't work with Plug&Play.... so it abstracts the hardware a little - but you have to plug in custom drivers to use it, and if you configure it wrong (which is easy to do) your system dies. Cool design guys! Typical of MS.

>   puts them far beyond MacOS which is tied to one particular
>   set of hardware still executing binaries from the last
>   cpu family in emulation.

BZZT! WRONG!

What do you expect from Windows trolls.

>   Any RISC versions of NT are native.
>   That cannot be said for the 'RISC version' of MacOS.

What does that have to do with what we were talking about? Changing subjects like that is called a "dodge". Nice try though.

> So.. essentially... this is the MacVocate position:
>
> Win/NT does not support features not supported by the
> underlying hardware, therefore it is shitty.

No. That WinNT is only running on a minority of the systems (about 1/10th the Macs)... so its not mainstream. It doesn't self-configure hardware, and has lots of issues with configuration, has lousy documentation, is not that stellar a performer or that powerful compared to VMS (which is was modeled after) or Unix (its competitor)... etc., etc... all things that would go towards calling something a "Shitty" OS. Yes it has a slightly better scheduler and protection scheme than the MacOS - but an OS is a lot more than just a sheduler.

Win95 which runs on more of the Wintel platforms has crappy plug&play compared to the Mac... has weird compatibility issue with older apps. Runs on DOS - but a little less than the past. Has shitty memory management issues like those low-mem shared globals for GDI/MDI that you can fill up and crash the system, it sometimes is CMT and sometimes PMT... it is the bastard child of all MS OS's that came before it, and is typical MS hacked up garbage.

DOS and Win31 aren't even worth talking about... as even most MS worshipers will NOW admit they they always have been garbage and always will be. (They will do the same for Win95 and the current WinNT in a few years as well).

> MicroSloth does not have a draconian stranglehold on the BIOS
> vendors. M$ has to implement over what it is given. This is
> quite distinct from Apple's 'big brother' position over Mac
> hardware.

Not true... MS could have put in their own BIOS HAL layer from the first version of Windows. They didn't... and they got bit by it... thats THEIR fault - no one elses.

> >Also note, I didn't start that thread - I just reponded to your

I
>
> Translation: Apple has an advantage that Microsoft does not.

More that Apple avoided a problem that MS did not. Its called thinking ahead or engineering.... its something Apple does better than MS. But MS markets crap better than Apple.

> >know WHY MS has problems doing so - but that doesn't change that

the

>   Translation: If Microsoft cannot match Apple, even with a
> unsurmountable handicap, then it's product 'sucks'
>   You don't even understand what you're talking about.

No. Its much simpler. If an OS can't abstract the hardware well - one
of the most basic functions of an OS - it seems pretty idiotic to call
it a good OS.... unles you are an MS troll... then its par for the
course.

> >The point is the Mac way is still better. The Mac WILL allow

video card.

No... it will allow you to add a DOS command line ONLY on the second
card. Big harry deal. Thats not using the extra desktop space - that
allowing you to debug your crappy OS or Apps in a command line. <Yawn>
I know this may be exciting to PC types... but Mac users expect their
hardware to work right.

> >I have 3 monitors at work, and adding a second at home again (I
used

> >work right (the way it should) anyways.
>
>   This is pure fabrication based entirely upon bigotry.

Nope... pure fact based on using both. Duh! I'm an engineer, you
simpleton, who programs both.... and I've got large company IS Dept.
support. And I work with lots of other engineers on lots of platforms.

Everyone with a room temperature or above IQ, and who has seen a Mac
w/MM's, realizes that the Macs multi-monitor support is better than
the PC's... which is really non-existant. (I don't call a debuggin CLI
window on a seperate monitor dual monitor support in the way people
want to use it).

>   You have no basis for this assertion. If MacOS is so
>   'superior', such tactics should not be necessary.

The basis is fact. You position is based on ignorance. Fighting for truth against ignorance of most DOS-trolls is what us Mac users are forced to do all the time. So fighting ignorance is necessary.

> >Lets try this.... you can create good turn-key solutions with PC's.
If
> >a PC comes pre-set-up, and pre-configured to run one or two apps,
> >etc... then the PC's are not bad solutions.
>
>   So? How is one graphical menu significantly different from
another.

One is at the top of the screen so you cant overshoot it... the other may be anywhere on the screen (see non-predictable location), can be overshot (which requires a sorta dampening effect to actually hit the target), can wrap around and be two lines of menus (making vertical hits even harder), the Mac cuts angles on hierarchical menus better, the Mac handles scrolling menu's better, Macs handle menu updates faster/smoother, etc., etc...

> >But if you want to actually use a computer AS a computer... to add
an
> >app, to change a configuration (without it blowing up in your
face),
>
>   Just what do Mac users find so hard about hitting the return key
>   several times?

Nothing... when that works... but its like playing russian roulette. You don't usually get killed - but when you do its most unpleasant.

Example - a co-worker plugged in both a Parallel Printer (HP) and Drive (EZ drive). Drive would work until you printed something - the pass-thru cable was a sick joke that is not really supported. Brilliant.

I tried to use a different printer after my Win95 machine was up and working... had to chase down the CD-ROM... (on the Mac I did the change and it just worked - no re-installation)... when we did that printer worked... but another printer wouldn't work anymore, my network connection started getting tempermental, etc... typical PC crap. Sometimes it works, sometimes it doesn't.

>   Also, just what configuration changes will blow up in your face?

Mentioned above... but there are dozens or THOUSANDS of others. I've had sooo many over the years with all those bullshit IRQ's and COM port conflicts its not funny.

>   Adding a printer is quite trivial as well. If it isn't a relic,
>   the current revision of the OS will install it for you.

Nope... it will install it *sometimes* if you ask it, and it *may* work (actually usually... but that not like the Mac which is 1,000 times closer to always).

> >better. Users can understand things easier on a Mac, and more
things
>
>   You've yet to mention why or give some concrete examples.

Why? Your mind is closed.... it wouldn't do much good.

I could mention file paths... or having to MAP network drives to letters and how fucking archaic that is.... I could mention shortcuts that fail when you move something..... long file names that can't have any special characters... and go on and on and on... but you will blindly argue that its OK because MS is great and their shit doesn't smell... etc., etc...

> >companies when you have IS depts. that are paid to maintain your
> >machines, etc. the PC is not nearly as bad as in the home).
> >
> [analogous tripe deleted]

And valuable points ignored I see...

Zip yes.  CD, probably not since I know of no Win95 bootable CD.

>Before under Windows 3.1, I tell you one thing---I had conflicts involving the ATI Mach 64 driver with another driver trying to use COM4. There are video drivers before that reserve certain I/O addresses and COM ports. Network cards and sound cards also compete for available IRQ and I/O addresses. I once had a EIDE driver that didn't like my video card driver as well (happened once in Windows 3.1, then in a totally seperate occassion, in OS/2.)

Chris, you're describing IRQ/BaseIO conflicts. These aren't exactly the same as having two drivers stomp on each other. These are strictly hardware limitation.

>I think when drivers are shoved into the same kernel space, there is a chance that conflicts do exist.

On the PC, if there is going to be a conflict in kernel space with drivers, the drivers can't be loaded--it's just that simple.

This is getting silly enough. Both the PC and the Mac has some kind of common denominator in the video that allows a video card made to that denominator run without a driver. In the PC we call it VGA or SVGA or VESA, and you can run a Matrox on those modes without the Matrox driver. I have no problem running the Matrox Millenium on 640x480 on 256 colors with DOS games without a dedicated Matrox driver, nor using OS/2's GENGRADD, run the Matrox at 1024x768 resolutions up to 16 bit color *without* the Matrox driver. (Not possible with Windows however.)

The drivers, on the other hand, are needed if you want to fully exploit the specific capabilities of the Matrox card---hence your true investment on that card. Otherwise you are just better off buying a cheap video card.

Before under Windows 3.1, I tell you one thing---I had conflicts involving the ATI Mach 64 driver with another driver trying to use COM4. There are video drivers before that reserve certain I/O addresses and COM ports. Network cards and sound cards also compete for available IRQ and I/O addresses. I once had a EIDE driver that didn't like my video card driver as well (happened once in Windows 3.1, then in a totally seperate occassion, in OS/2.)

I think when drivers are shoved into the same kernel space, there is a chance that conflicts do exist.

Yes, you can boot Windows 95 from Zip drive and CD-ROM drive. Most newer motherboards in the last one year has Bios that supports bootup from CD-ROM drive.

Why couldn't you burn one? Assuming you've got an El Torrido or
somesuch-friendly BIOS, what's not to work?

If you spend the time and money to get a Win95 bootable CD burned, yes you can certainly boot Win95 from a CD. Most decent SCSI controllers will allow you to boot from a CD--almost all of the new motherboard BIOS will allow you to do the same.

However, while the Mac has a bootable CD widely available, Win95 doesn't. Which is the reason why I made the comment.

That's why it was a shockingly recent development. In any case, the Amiga insists on closing all windows on the WB prior to changing WB resolution, which can be a bit annoying if you use that as your main public screen.

YEP,
MOST PEOPLE WHO USE MACs HAVE NOT NOTICED THE CURRENT MAC/OS HAS A DIFFERENT "multitasking" THAN (1) PREEMPTIVE MULTITASKING
(2) ETC.
(2) ETC.
(2) ETC.

LIKE YOU THEY ARE AMAZED HOW MAC USERS WORK ON TWO/MANY PROCESS AT ONCE - EG. FORMAT FLOPPIES & HARDDISKS, DOWNLOAD & PRINT VIA PPP, ARA, IPX RUN WIN NT APPLICATIONS AT PENTIUM SPEED, APPLE][AT FASTER THAT REAL HARDWARE, RUN DOS7 & WINDOWS 95 ALL AT THE SAME TIME (THE COPY PROGRESS BARS MOVE WHILE THE REST GOES ON!

YEP ALL AT THE SAME TIME!!!!!!!!!

I HAVE HAD 31 CRASHES SINCE INSTALLATION AND RUN 28 EXTENSIONS ON STARTUP. THIS 88MB 150MHz 604 (MORE POWERFUL THAN A PENTIUM PRO 200MHz in Bytemarks) is now 7 months old.

Yep you should be amazed the current MacOS does all that without etc. etc.etc.etc.

But it still holds years of advantage over Win NT and DOS7 & Win95.

It was 32bit long before Windows NT and as well all know Win95 is not a true 32bit operating system.

I am more amazed how few DOS7 & Win95 users can copy files from different locations concurently.

By the way - without any addin PCI card I background my high speed comms at 115,200. Is that slow?

I use all characters but the ":" in my filenames!!!
Do you get amazed at that??
I wouldn't be amazed if MS-DOS/NT/UNIX users couldn't I bet like the Mac users they don't miss the little differences!

I don't however recall that the Windows 95 CD ROM itself is bootable.

Nope it isn't.
The Win95 CD actually has all the setup files in a compressed format
(.CAB files). It also has a bunch of documentation, drivers, etc...

To boot Win95 from a CD, you'll have to burn one.

Yes, I mean Windows 95. You just need to burn in the system and Windows 95 files to the CD-ROM.

You need to copy (burn in) the system files in the root directory and
the Windows 95 folder to the CD-ROM. And this CD-ROM is bootable when
the Bios supports it.

You got this mixed up with the Windows 95 Installation CD-ROM.

Power without the Price was Atari's idea for a slogan. And a load of Crap.

It defies logic and goes against All the Laws of the universe. Like "A Man is worthy of His Hire." and "You get what you Pay for." and "If it sounds too good to be true, It's probably a Lie." and in Atari's case, "You sow what you reap" aka "What goes around, comes around." Atari trying to appeal to cheapskates was it's undoing. Don't punish Toad because of an Atari Slogan. They're trying to support Atari, stay in business and feed their families. I just received a Toad-M SwitchBox which will let me use a MultiSync Monitor on my Atari ST to do Color and MonoChrome on the same MultiSync. This will also be the Last one Toad makes as their Technician is leaving because not enough people wanting to keep him Employed with a DEMAND for work. I know about the Crap that Bonafide Atari dealers put up with. And how many don't appreciate them. I blame it all on Atari, especially their slogan "Power without the Price!"

:>NT seems to be good ride right now, too.

I think NT is overrated. For an industrial strength OS it seems to have a few stability holes. I hate to see people support MS if they don't have to. MS is trying to replace open standards with proprietary MS standards, that alone is reason enough to stay away. What Microsoft wants, and you can see this by looking at NT server setups, is an MS server with MS clients. The clients can be nothing more that Windows "terminals" controlled by the sys. admin. All software can be monitored, installed, and usage tracked, from a central location. Now this is not inherently bad, but it smacks of the IBM mainframe and dumb terminal paradigm that everyone complains about. Lets face it. MS has become IBM. At least IBM has made Warp compatible with open systems, i.e. TCP/IP, OpenDOC, CORBA, Java. etc.

Wooow I should have bought a PCI Mac, and then add a PCI ATI or Matrox card.
(Never had a Mac that used an add on video card before.)

The only way that's possible is if the video card was designed to follow a tight
spec set by the software set within the system itself, and not the other way
around. The actual "driver" of the card must be in a ROM within the card
itself.

Burn my Windows 95 CD?   Isn't the roasting treatment a bit extreme even for
me? :-)

Rgds,

Chris

Idiots because we realize that there has to be something around telling
that ATI Rage II not to act like a Cirrus Logic 5428. The OS may just
hide it from you but, it needs to be lurking in there somewhere.

>video cards on the Mac which require any software (other than the what
>is inherent in the OS) to run them. They are plug-and-play in the purest
>sense of the word.

...until someone comes out with a new chipset...

oops... time for another OS revision, so they don't realize they
got autocad drivers under the hood... '-p

BTW, according to your twisted definitions, Win95 (and probably NT) still
supports Multiple monitors. The dirvers are sitting right their with the
rest of the STB drivers. We can even look through them so's, we can make
sure that X card wont be stuck in nothing but vga modes...

It abstracts it sufficiently enough that a 500Mhz Alpha will
run at full native speed. Considering that MacOS would not
be capable of doing so, that is an acceptable tradeoff. Really,
what's the point of buying an X704 just to run an OS that's coded
in 68K?

>drivers to use it, and if you configure it wrong (which is easy to do)

You were the sorry fool that mentioned HAL's. That IS what HAL's
are for you know. If the MacOS had one, it still wouldn't be running
parts of it's OS as 68K.

>

Shitty compared to VMS != Shitty when compared to MacOS.
If you insist on such comparisons then MacOS looks very much
worse than it already would.

So? What's it missing in respect to VMS and Unix? Do tell?

>
>Win95 which runs on more of the Wintel platforms has crappy plug&play
>compared to the Mac... has weird compatibility issue with older apps.

The only compatibility issues that arise are due to tighter system
protection. Programs break when they don't behave nicely. This,
ideally, is what an OS is supposed to do.

Win95 plug-n-pray is of course crappier. There is much more for Win95
to do. It has to deal with hardware that could concievably be older
than any Mac or Lisa in existence. Win95 fails when compared to MacOS
in this regard; it also attempts to achieve more.

Subject yourself to MacOS limitations and the vast majority of those
problems should dissapear.

>Runs on DOS - but a little less than the past. Has shitty memory
>management issues like those low-mem shared globals for GDI/MDI that
>you can fill up and crash the system, it sometimes is CMT and

Dunno about that. I push systems past the edge and I've yet to
run out of USER or GDI segment space on a Win95 box. Perhaps you
could provide some examples? Just what were you doing in Win95
when the GDI dried up? That way we can all reproduce it...

>sometimes PMT... it is the bastard child of all MS OS's that came
>before it, and is typical MS hacked up garbage.

The only problems I really have with Win95 is large scale file
management. Moving around 100M+ or 1000+ files tends to clobber
the explorer. I have the same problems with Moxfm, however.
Neither can acutally crash the system however...

>

>thats THEIR fault - no one elses.

     You are truely clueless.

     No amount of cursing, wishing, or praying is going to keep an
     OS from NOT being at the mercy of the hardware it is running on.
     This 'hardware' also includes the BIOS.

     Those fiddly bits are not going to magically jump off, run over to
     the disk controller and start it up. THAT bit of magic needs to be
     on the mainboard. Until those fiddly bits have finished thier job,
     even VMS is at their mercy.

     None of your whining is going to change that.

>

    It is little wonder that a Macindroid is incapable of making the
    distinction between hardware and software here. There is plenty
    that MicroSloth can actually be blamed for. Go hark upon that
    instead of making the Mac look foolish.

    When Microsoft starts manufacturing BIOS chips, then you might
    be able to complain.

>course.

There is nothing to abstract at that point. The entire bootstrap process occurs before the OS even has an opportunity to get to the system.

Even an honest Microsoft hater would defend them upon this point. There is really no need to invent things against them. Such dishonesty only paints them as a sympathetic victim.

You are doing that quite nicely...

Actually, it will allow you to add an NT debugging console. That can actually be quite useful for those of us who know what their doing. Not all of us need pictograms to get work done...

>allowing you to debug your crappy OS or Apps in a command line. <Yawn>

>support. And I work with lots of other engineers on lots of platforms.

For an engineer, your lack of understanding of the hardware you are
using is quite appaling. If you have a PE (or any other) licence it
should be REVOKED!

As an engineer, trained in science, I can judge the universe based upon
my observations. My observations to this point have not yielded anything
reproducible. Therefore, I can neither confirm nor, deny your babblings.
Since you don't even understand the rudiments of a computer's bootstrap
process, it would be a fair assumption that anything you say is bogus.

The some total of my observations may change at some later point in time.
At which time, my conclusions may need to be revised. However, I don't
think that there is much likelihood of that happening.

>

'better' is a qualitative statement.

>window on a seperate monitor dual monitor support in the way people
>want to use it).

It seems that you aren't willing to actually ask people how they
want to use it. Furthermore, THAT wasn't the only solution stated
by myself (or others). STB has solutions available and those are as
plug and play as any Mac solution.

Furthermore, monitors beyond the 30" size range are quite commonly
available in 'engineering'. In that domain, multiple monitors seem
more useful as a gimmick than anything else.

>
>>   You have no basis for this assertion. If MacOS is so
>>   'superior', such tactics should not be necessary.
>
>The basis is fact. You position is based on ignorance. Fighting for

Go back to college, 'engineer'. Stating an assertion repeatedly
does not make it a fact.

Were you capable of doing otherwise, you might actually succeed
in making me appear ignorant. That you've gone this long without
providing reproducible examples would appear to indicate that you
are not capable of it.

>truth against ignorance of most DOS-trolls is what us Mac users are

>hits even harder), the Mac cuts angles on hierarchical menus better,
>the Mac handles scrolling menu's better, Macs handle menu updates

The value of scrolling menus is nil. You have taken a device
useful in limiting information and turned it into a storehouse.
If you want to bombard users, you can just forgo the GUI and
bombard them with man pages.

>faster/smoother, etc., etc...

There's not that much on a menu to handle, or rather there
shouldn't be.

BTW, I wasn't aware when hard drives became applications.

The russian roulette part is attempting to use a Parallel port
as a SCSI port. Why didn't they just give her the internal IDE
version?

>
>I tried to use a different printer after my Win95 machine was up and

Just how does it hinder you?

>that fail when you move something..... long file names that can't have
>any special characters... and go on and on and on... but you will
>blindly argue that its OK because MS is great and their shit doesn't
>smell... etc., etc...

Some shortcommings are more significant than others. Of course you
would have to hark upon the most superficial problem with VFAT,
ignoring the more significant ones, the ones that can actually cause
problems.

Given the choice between forgoing colons in my filenames vs. loosing
data, I'd dump the colons...

In Wintel this is called VGA.

So much for the myth; that explains quite a bit now.
Plug-n-play doesn't seem quite as impressive when one
realizes it is nothing more than a warmed over version
of VGA. Admittedly, such a thing is useful but, it is
hardly remarkable.

Macintosh: It will be plug-n-play but, only if it's a vga card...

ATARI PROTOTYPE AUCTION #1:

The following RARE items are available for auctioning.

RULES: Bids start at specified price and will go up in $10 increments.
Updates will be posted daily to all bidders. Auction will go until Jan
10th 1997 and will then enter the GOING, GOING TWICE, GONE stage. All

bidders who make it to the GONE section of the bidding are responsible for shipping costs. All items will be shipped PRIORITY ONE MAIL. Please don't bid unless you are serious about buying. All items are sold "as-is" and there will be no returns and/or refunds. No items will be shipped until payments are received and cashed.

Atari SALT Diagnostic Module: Enclosed in an Atari 850 interface, has 1 Serial SIO port, 4 Atari RS232 ports, power input, an RCA plug where the Parallel intreface would normally be, and 2 14 pin chip sockets, an HP seven segment ultra-bright LED display and reset switch. Unit powers on and doesn't cause any Atari that was hooked up to it to freeze.
Salt Diagnostic ROM or disk software required to activate and use this unit (NOT INCLUDED), picture available on my web page upon request.
(3 Available) Minimum BID: $50.00ea.

Atari XL Salt Diagnostic Module: Enclosed in an Atari 850 interface, unit has PBI cable comming out of right side SIO connection cut-out of 850 module for testing parallel bus interface.
Salt Diagnostic ROM or disk software required to activate and use this unit (NOT INCLUDED), picture available on my web page upon request.
(1 Available) Minimum BID: $75.00

EXTREMELY RARE: Atari 6402A Prototype Motherboard (only 3 exist!!!)
Prototype motherboard, apparently a test bed which has all the same components contained on an Atari 1450XLD "TONG" version motherboard including disk drive controller area, modem area, SC-01 voice synthesiser, Parallel Bus Interface. This unit has ports positioned on all 4 sides and does not appear to be a "commercial" product but appears to be more of a test design to condense the Atari 1450XLD TONG motherboard down to about 1/2 the size, (unit is NOT functional)
Minimum bid $120.00
Image will be posted on my webpage upon request

Atari XE Game System 8 port multicart prototype board:
A prototype test board which may have been a pre-design idea to allow the XE game system to contain and select up to 8 cartridges (this of course turned out to be built in BASIC and MISSLE COMMAND in the released version) The board is about 8" by 12"
Minimum Bid $50.00
Image will be posted on my webpage upon request

Atari XEP-80 Prototype:
Atari Corp design prototype of the XEP-80 system. Design consists of a mainboard, daughter card, DB-25 connectors and Atari joystick interface cable, this unit has never been tested and I am not sure if the current commercially released XEP-80 software will work on this pre-design prototype.
Minimum Bid: $75.00
Image will be posted on my webpage upon request

Make all bids and requests for images to:

I don't know Mr. JEDI. Does ATI make a version of the 3D Expression+TV board to work with the Mac? If so, I will gaurantee that it doesn't need any drivers to display any resolution, screen size, or any bit-depth that the board displays.
It probably would need a control panel for the TV part and possibly the 3D part, however. But, if you think I am trying to say that Macs never need enabling software for add-on boards or other peripheral devices, then you haven't been paying attention. Macs don't need drivers for monitor video cards to display video at all supported bit-depths, screen sizes or resolutions PERIOD! No other functions are either stated or implied by me.

That's funny, there have only been Macs which can use add-on video since 1986! The first Mac II, the Mac IIX, the Mac II CX, Mac II Ci, Mac II FX, various six slot towers such a s the Quadra 900, 9100, 9500 had NO on-board video. One had to use plug-in add-on video cards. Any Nu-bus or PCI or PDS (processor direct slot) Macs can use add-on video cards. Most don't require them, however, unless one wanted to drive a larger monitor at a higher bit-depth than the on-board video allowed

>
> The only way that's possible is if the video card was designed to follow a tight
> spec set by the software set within the system itself, and not the other way
> around.

I have been saying that for more than a week in this thread. The system contains all that is necessary to drive all Mac compatible video boards, whether you are running just one monitor, or six contiguous monitors (that means that the computer treats all of the connected monitors as if they were one big virtual monitor. The cursor will move from one to the other accross the screen boundries as if the boundries weren't there) -of course you need a Mac with six board slots to do that (like a 9500). Most Macs, PCI or Nu-bus, only have three expansion slots and "pizza-box" Macs only have a PDS slot.

The actual "driver" of the card must be in a ROM within the card
> itself.

I don't know. Its a non-issue to the user. It just seems like a much more elegant solution than the Windows route (but, then, isn't almost anything?) ;<)

Wrong. Mac Video is NOT VGA! Not only that but video plug-n-play
has been a fact on Macintosh SINCE 1986! (so who has warmed-
over what?), and 24-bit color has been available on Mac since
1987.

Plug-n-Play on the Mac is sooo much more than that! Its
plugging in a scanner and having it work first time every time
Its putting a 3D renedering board in a PCI slot, droping an icon
on top of the system folder (where the system then tells you
where its going to put the Control Panel or Extension and why),
and then restarting the machine. The new board is recognized
INSTANTLY, and EVERY TIME!!!! Try that with MS 'Plug-n-Pray'.
And, if its not so remarkable, how come PCs can't do it
reliably, and how come they left it out of NT altogether?

"Enquiring minds WANT to know"!

Wrong! Mac video cards are written to the Mac video spec or they don't work at all. That spec has not changed appreciably since the advent of 24-bit color. How do I know this? Because NO video card I have ever seen comes with any system revision cavaets per se (obviously, a PCI video card won't work with a system that doesn't support PCI, but that's another issue, having nothing to do with the video spec itself). If you want further proof, go to a library and take a look at the book(s)* "Inside Macintosh". It (they) contain all of the info required for anyone to write software or build hardware for the Mac. You'll be surprised how little the Mac video spec has changed over the years.

I don't understand what you are getting at in the above paragraph. Please illucidate. Thanks.

George Graves

*"Inside Macintosh" has been published as many volumes with new ones coming out to cover new enabling technologies as they emerge (something you W/Intel folks never have to worry about;<)). But compendiums of the set covering only recent models (with pertinent information from earlier volumes included) also exist. So one might be confronted with a single volume or multiple volumes going all the way back to the original Mac 128.

In 1988, the cheapest PC Clone available in my area was an (PB)
8Mhz, 8088, w/ 640k & 10Meg HD, dual 5.25 floppies and a cga card.

It cost $1000.

A 520ST (w/ SS drive) cost $300.

Despite the appearace that that Clone outspecs this ST, the
ST ran circles around that machine and was quite a bit more
useable.

Just because you can't manage it now; it doesn't mean that it
never was.

Power without the Price, existed once.

It is not a far stretch to say that that is why many of us are here.

"Slightly" better scheduler and protection scheme?

Ahem. :)

"Slightly" better then MacOS7, which has poor and none. :)

>Everyone with a room temperature or above IQ, and who has seen a Mac

While I agree that the Mac has better multiple monitor support than the PC, it is wrong to say that the PC doesn't have it at all.

Try:

http://www.appiantech.com/a2.htm
http://www.appiantech.com/j2.htm
Dual monitor support for NT and 95 using dual Appian video cards.

http://www.matrox.com/mgaweb/brochure.htm
Note where it says multiple monitor support for NT under "Ultra-High Resolutions & Colors" section.

>faster/smoother, etc., etc...

Actually, I don't like the way the Mac has it. Personal preference really. I like to have a visual association between the app and its menu. I find it less confusing overall.

When is the Mac going to get a decent keyboard interface for the menus? Most of the time, I use a Windows program with one hand on the keyboard. (Two if it is an editor or word processor. :)

On the Mac, I find it a lot harder to do this without looking up esoteric Command-Key combinations because Windows menus *display* as I use the key combinations, unlike on the Mac. sigh.

Personally, though, I'd prefer context sensitive right button menus (which I can also get to via Shift-F10 (or some key combination) if necessary).

Ideally, the top menu bar really only *needs* six options: Create New, Open Another, Send To, Save Changes, Save As Another Document, and Discard Changes.

Send To should have "E-mail User", "Printer", and others as sub-options.

Other *document* actions can go here as well as on the context menu for the desktop icon for the document.

You shouldn't really use Open, because you can just open a document from the desktop by double clicking, or by using its right button context menu. (This works for things like network connections as well - treat a network connection as a document on the desktop.)

You shouldn't really use New, because you create new documents by dragging from a template or using a "Create New..." option from the desktop right button context menu.

All other menu options should removed from the top menu and instead be tied to context sensitive right button menus for the objects that they are valid for. Global tools should be available in floating dockable toolbars, with automatic flyout textual names.

For example, if I want to make a line of text bold in my word processor, I'd select the text, click the right button on the selection, and click bold on the context menu. Easier than selecting the text, moving the mouse all the way up to the top of the screen, then looking for "Format", clicking it, looking for "BOLD" and clicking it.

As another example, what if I want to cut a piece of text. Select the text, right click on the selection, look for and click "Cut".

Easier than selecting the text, going all the way up to the top of the screen, looking for and clicking "Edit", then looking for and cliking "Cut".

Let's say I want to go back a page in my WWW browser.

It is easier to right click anywhere on the page, look for and click "Back" on the context pop-up menu.

It is harder to find the "Go" menu at the top of the screen, move the mouse all the way up to the top, click on it, then look for "Back" and click on it.

It is harder, as well, to move the mouse up to the Back button on the toolbar. (Though even the toolbar is a better solution than the top menu in this case.)

If I want to spell check a document, I right click anywhere blank on the document page, and select Spell Check from the context menu. Simple.

The idea is that if I want to work with a "something", I don't need to move the mouse all the way up to the top of the screen and read or rummage about with menu options that have nothing to do with manipulating a "something".

This simplifies the UI for the user, since actions which are not relevant,
are not displayed, and mouse movement is reduced a lot.

It frees up screen real-estate, since no unnecessary menus are available.

Furthermore, all actions are directly associated with
what they are acted upon.

Once the user discovers the basic concept of "select the thing you want to
change, and click the right mouse button", things become simple, and fast.

Windows is closer to this than the Mac is, though. OS/2 is closer than
either of them, but OS/2 has other UI problems. :(

UI design is, of course, a very subjective thing. My version of the ideal
UI can, and probably *is* different from yours. :)

Sure NT has holes.
```

So do all unices (as evidenced by the large number of CERT reports that seem to arrive in my mail box)

So does public key encryptation (eg: the Kocher attack)

So do AIX systems (the notorious login -r bug , eventually fixed by IBM after it was described on the net comes to mind)

So do AS400 systems.
(BTW, a client who worked as a systems engineer on AS400 systems claims that most of them still have the original 5 letter systems engineer password on them. He claims that he telnetted across the world across corporate systems using this .... go figure ...)
No , I am not going to post the 5 letter password here... although hunting through old issues of phrack sure is informative.... :-)

Heck if your secrets need Fort Knox type security, put them IN Fort Knox !

If you absolutely need a crashproof system, invest in a fault tolerant Tandem system with dual controllers, mirroring, dual cpus ,
dual everything and have a parallel system connected by fibre optics mirroring your original but placed miles away.
Then sit back , pray and prepare for the inevitable crashes ! That is what the TPC intensive sites (banks, Visa , stock markets) do.

No, little old NT simply is not in the same ball park...
But it and Linux sure are stable enough for my simple needs...

"It is a tremendous Mitzvah to always be happy! "

Nah, it'd probably come bundled with Windows 95. :-)

    It makes a PCI version of that card actually.
    Since the current macs claim to be able to use PCI card's,
    then your spiffy mac should be able to handle it.

    This should be the case regardless of whether or not that
    particular PCI card is nothing more than an Uber-VGA card.

>to display any resolution, screen size, or any bit-depth that the board

   In other words: Mac Video Cards are plug-n-play so long as they
   conform to the Apple equivalent of VGA.

   WHO CARES!

   PC's had 'plug-n-play' of that 'sophistication' long before macs did.

   I have been paying attention... all too well.

WHO CARES!

PC users view VGA cards as about as useful as you would appear to
view hercules cards. It also seems bizzare that anyone who would care
about high end parlour tricks would settle for VGA++ of any kind.

```
   You've shown Apple Plug-n-play for what it really is...
              ...a set of cloning standards.

   Even Billy-Boy could manage plug-n-play in such restrictive
   circumstances.

    Yes, quite elegant:
         restrict user choice to the point that integration is trivial.

    It's positively Orwellian.

So, call it VGA++. It is still the same essential idea as
hercules, cga, ega, mcga & vga. The Spec is castrated to
aid in integration. It may be a good design descision but,
it's nothing to brag about.

>
>Plug-n-Play on the Mac is sooo much more than that! Its

All of this is rather easy to do when you so brutally restrict
what the system will accept. You're really lowering the bar,
nothing more.

A PC can use Scanners and 3D boards that simply wont work with a Mac, no matter how hard you try.

If PC hardware were so constrained, PC integration would be no less difficult.

>INSTANTLY, and EVERY TIME!!!! Try that with MS 'Plug-n-Pray'.
>And, if its not so remarkable, how come PCs can't do it
>reliably, and how come they left it out of NT altogether?
>
>"Enquiring minds WANT to know"!

Why? Because PC's support a greater diversity of hardware, a greater diversity of bus options and aren't merely limited to cloning someone else's spec.

They aren't merely limited to IDE boards, VGA cards, Sound Blasters and the like.

Windows Plug & Pray attempts to achieve much more than the Apple version ever dreamed of. The Apple version is nothing more than a clever way to stack the deck. Apple has ordained what it will support and left the rest to rot. There is nothing remarkable in this restriction. When held up to the light, it acutally looks rather fascist and cowardly.

What computer was born in 1984?

Actually they aren't (at least not NT and 95).

UNC names work fine.

I think that we will need to find out exactly how all the SPECmarks are generated before we can compare them in any meaningful way. I especially wonder why the numbers that you gave were so different from IBM's estimated performance. I really suspect that the workstation test was not using FMADD instructions which would account for the very odd floating point results.

> >I am amazed that Windows (NT, 95, CE) doesn't have scriptable applications
>
> You haven't been looking very hard or are just lying? Word and Excel are so scriptable they have their own virii.

They are CLOSED scriptable... you can script inside of them - but not across them and other apps. The Macs SYSTEM AND APPS use the same scripting mechanism.

Example - on the Mac I can open a spreadsheet, create a file, save the file, have the script select the file from the finder, move the file across the network, then open a different App, import the file - save the new file (in a different format), then delete the old file. That is scriptability and the type of thing you cant handle on Windoze. EACH APP must have its own scripting capabilities - different from every other app.

> >I am amazed that Windows (NT, 95, CE) can't boot from a removable SCSI disk
>
> This depends entirely dependent on the BIOS, not the OS.

But the point is that on the Macs it works... period... on the PC's it may work under certain circumstances... or it may not.

> >I am amazed that Windows (NT, 95, CE) can't use 4 monitors at once
>
> This is also WRONG. Troll around the STB homepage. The PC solution is different.

The point is that on a Mac you can take 3 different video cards - off the shelf, and use the internal video, and drive different monitors with different resolutions and display characteristics and have one large workspace... and have concepts like main monitor and UseBestResolution/UseBestColorDepth/etc.... you can not do under windows - and the "solutions" that allow more than one monitor are proprietary hacks that may or may not work well with other things.

> >I am amazed that Windows (NT, 95, CE) can't be booted out of RAM

>
> I think that the Atari ST/TT/Falcon would be the only ones capable of this feat. MacOS was never small enough to manage this.

Huh? I've booted off RAM disk quite a bit... lately its getting harder - but it was not uncommon (though not common either). In fact the Mac Classics had a ROM disk to boot off of. Boot one while holding option-command-x-o... no hard-drive or floppy need be attatched. (They were going to do some diskless serving stuff, but never finished it).

> >I am amazed that Windows (NT, 95, CE) can't be used by my mom
>
> Perhaps my mom should teach your mom.

Perhaps his mom should teach your mom that you should be a computer expert to use a computer.... sorta like you shouldn't have to be a auto-mechanic to drive a car. But if you own a Jag it helps.

Umm, no.
Dfs (that's captial D, lower case f, lower case s. DFS is trademarked
by Transarc) is somewhat orthogonal to the issue.

I agree, Dfs is nice. But that is more along the lines of keeping
sysadmins (and users) sane regarding multiple mount points (ie.,
ridiculous number of drive letters for network shares).

The use or non-use of drive letters at the local machine is purely
shell dependent. In the case above, I used a shell called 4NT.

Too big. 8-)

Even NT's ping implementation (which has the bug of letting you pass a bogus sized ICMP packet) won't accept that large a packet.

You're thinking of 'ping -l 65510 blah.blah.blah...'

Actually, at my alma mater, there was (until this fall) an entire roomful of diskless Mac LCs that ran the OS off a RAM disk. System 7.1, though.

This is more mac FUD. What advantage a mac system may have over
a PC is most probably due to memory interleaving. When compared
on a more even footing in this regard, Pentia actually perform
BETTER than PPC's.

Considering that only certain mac clones seem to have this, even
this benefit doesn't seem universal. Note how only certain PowerC
models allow one to optimize the simm layout for maximum interleaving
benefit.

I've yet to see a benchmark in which a PC was bested where issues
like these were addressed. When they are, Pentia end up being faster.

>require a Pentium system running at a 20 to 40% faster clock speed to
>equal it.
>
>   The best PC for $2K I could find (quality PC, that is, not Packard
>Bell) was a Sony AVIO at COmputer City. I was far from impressed.
>Incidentally, it was a Pentium 166.

Considering that this system likely has feature improvements over any
of the macs in it's price class or features not present at all in
equivalent macs, it's not a completely honest comparison. Typically,
the only machines that match mac features are the Packard Hells.

The video specs are especially amusing. Given the lack of detail they
are presented in, Mac video specs seem to compete only with the
generica. 1Meg 64bit video without 3D acceleration would be considered
very substandard on any brand of PC that a MacVocate would call

'quality'. We're talking bottom of the barrel here...

Then there is the low end SCSI2. Excepting bootrom, this is also the
very bottom of the barrel wrt PCs. Furthermore, SCSI2 underperforms
IDE Mode 4 which is quite commonplace on even cheap PCs, not to mention
the ones a MacVocate would call quality.

Excepting disputed cpu benchmarks, most macs can only compare to the
Packard Hell's. To do otherwise typically would require upgrades that
quickly make a mac of any kind loose price advantage.

[deletia]
>604's outperform Pentiums at equivalent clock speeds on all levels.

No they don't. To say so is blantant intentional misrepresentation.

Furthermore, it wasn't relevant to the comparison.

[deletia]

>Macintosh.

IC. So, you are saying that the greater number and variety of
expansion slots, extra device capacity on the device chain,
extra device capacity on the floppy chain & a case that actually

has external drive bays is less expandable than a system with less slots, less types of slots, less availability of alternate motherboards, less availability of CPU upgrades, less availability of upgrades of any kind and no external expansion capacity in the case.

Hells are harder to upgrade relative to other clones. This in no way can be honestly construed as being harder to upgrade relative to macs.

>
>Your claim about Mac clone "stripping" is actually an apt description of
>Packard Bell and MOST bargain-basement PC clones. Ever try to replace
>the sound card, install SCSI, or add a CD-ROM on one of those? Most

Installing a SCSI card would be no less difficult with any PC. Neither would a CDROM. Other things would depend upon the level of integration. Even those would likely not be a problem as you can disable the onboard video, sound and such.

It is a Packard Hell, not a MacPlus.

>require HUGE expenditures in additional hardware because of their
>"bargain basement" rankings. Their quality is unacceptable.
>
>An APS low-end Mac clone includes 16 megs of RAM, 16 bit stereo sound,
>keyboard, mouse, a 1.2 gig hard drive, a 160 MHz 603e, IDE and SCSI,
>ability to use a VGA monitor and PS/2 mouse ports. Hardly a "strippo"
>system.

This quite aptly describes a Packard Hell, actually. Everything else tends to have more and better of everything. PS/2 mice tend come with DB9 adapters to that is no real advantage. Everything else, except the ultralowend SCSI, can be found on the Packard Hell.

Unless you like octopi, the slow SCSI2 has little real advantage over what is delivered even on a Packard Hell.

>
>Another thing you get with Mac? Real multimedia that's easy to use. PC
>multimedia is many years behind, unrefined, and a hodge-podge of
>BIOS-conflicting, IRQ-confusing, expensive, poorly-supported hardware

MacVocates: master of lies.

For 3 years, at least, multimedia has been plug-n-play at the hardware level. The smaller vendors have tended to mimic the dominant one to such a degree as to create a defacto standard in that regard.

The assertion that anything is expensive on PC's when compared to Macs is beyond absurd. PC's and ultracheap hardware can be problematic. This is something that Macs don't have however.

>and software. And since multimedia is what many people aim for (even if
>merely for games), people again get what they pay for.

$200 will get them as much plug-n-play multimedia as a CheapMac
can deliver. It will be from the leading vendor (Creative Labs),
will be well supported on any x86 OS (Linux included) and will
be quite well supported.

Who in macdom have their board digrams online?

If you knew what you were talking about, you might be able
to identify the real PC problems. As it is, you seem only
capable of sniping the PC at it's least vulnerable points.

>
>The multimedia capabilities of that $1,499 Performa 6360 or $1,399 APS
>blow the $1,299 Packard Bell out of the water.

So? What are they going to blow the Hell out of the water with:
sad dellusions? The Hell has the same sound capabilities, the
same cdrom capabilities and similar cpu power.

Add that $200 multimedia kit to a 4 year old 486/33 ISA system
and the APS or Performas wont even be able to 'blow' it
'out of the water'.

It would be nice if some concrete examples were given.
As of yet, you're just bluster.

BTW, the $200 Multimedia kit mentioned is the Creative Labs
Value CD 8x. It contains a pnp version of the SoundBlaster
16 IDE and an IDE 8x cdrom drive.

This is all there is to 'multimedia'.

>memory, only 32 megs on each "dumb terminal workstation" and 64 on the

I dunno about this. I have run full text retrieval database
servers & a webserver concurrently on a machine of this size.
(not to mention X & all the trimmings)

>server), we determined we had a defective batch of machines. Gateway

Pretty much a nobrainer.

>had to be screamed at, while we were down for over two weeks. Finally,
>the PCs were replaced.
>
>I went to install the new SIMMS in the server (to upgrade it to 128
>megs), and couldn't get it to work. Why? The BIOS had to be put

Sounds like an ancient BIOS.

>through some sort of arcane process before it would recognize the new

I wasn't aware that mac users thought that menu driven systems
were arcane.

>RAM. That network had so many problems that they ended up hiring a
>seperate hardware consultant, and, I understand, purchased a new
>server. Not a glowing endorsement of PC technology.

I have seen relatively recent Gateways being upgraded in that fashion. A BIOS reset was oddly absent. This anecdote seems quite a bit out of date. The last machine I saw with such an antiquated BIOS was a Wyse 386.

>
>In a Mac setting, the systems could have been installed by an entry
>clerk, with minimum help from me. Even if they had gone for the most

Much like the relative ease in which my wife upgraded her ram. Her machine is a skanky, 4year old, bargainbasement, junkware, Cyrix PC and yet even it didn't have such an awful BIOS. Perhaps MacVocates shouldn't pick on junkware quite so much...

>expensive, least-cost-effective Mac systems, they would have saved tens
>of thousands of dollars in downtime, new hardware, and consultancy fees.

I think you're full of it. Still you have not come up with any level of detail. Furthermore, you had to troll into the mail order domain to get it. I am also not sure about the decade in which that hardware was manufactured either.

PC's are the proverbial tortoise to Mac's proverbial hare. The PC's started out slow but have been slowly evolving and improving in an enviroment of rigourous competition. While, on the other hand, Apple has primarily rested upon it's laurels secure in the knowledge that their userbase is so devoted to them that they will never have go to the touble of maintaining that devotion by at least keeping up with MicroSloth.

In the end, Apple ends up groping for BeOS and NexSTEP as PC's slowly improve.

Even 3 years is an eternity in this enviroment. Despite this, the ease of adding multimedia to a PC has remained fairly constant. If you do manage to run into trouble such trouble definitely will not be accompanied by hardware that can be sanely said to be 'expensive'. Even the best, trusted brands will outperform Mac one's in price. However, other devices have become more standardized and a plug-n-play spec for ISA and PCI have come about.

True there will be some problems. However, if you restrict yourself to sorts of producst that pompous MacVocates would be willing to buy, you should not have any troubles. Despite this restriction, you will still have quite a bit of choice. You'll even get to browse for your selections physically, if you really want to.

>

MacVocates: they shower devotion opon a platform for ease of
use and then make their lives as complicated as they possibly
can on any other [platform].

Just run MSD, you rube.
The DOS installation utility will also likely tell you
what the necessary IRQ's and baseaddresses are.
Nevermind... there's always... tHe MaNuAl...

>various mixtures of IRQ numbers until you find the problem. Spend about
>four hours doing so. Assign new numbers that Windows NT 4 will find
>acceptable. Tear out hair. Reboot. Get new driver from hardware maker
>because it won't allow reassignment. Tair out hair. I've been through
>all this before, thanks. It ain't Plug and play, no matter what Bill
>Gates dreams it should be.

I don't suppose it would be expecting too much of you to have
checked the supported device list before going off half cocked.
Given your pessimism regarding PC's, such behaivor should be a
very minimal standard. This is especially so if you presume to
be a professional.

NT is quite a bit less tolerant than either MacOS or any other
variant of Windows.

With any other CDROM of any kind and any other MicroSloth OS,
you should have just been able to run the installation software
that came with the drive. Win95 even supports DOS drivers for
devices that aren't well supported on it yet.

So? What was that device again? Brand? Model? Interface?
Hell, you couldn't even be bothered to tell us what interface
it were using...

An IDE cdrom drive is plug-n-play EVEN IN LINUX.

At this point in time, as opposed to some distant year, THAT
is the vastly predominant CDROM type for PC's. Even 2 years
ago they were becoming somewhat scarce.

If you buy a PC TODAY, and in not some distant year, the commonly
available CDROM drives (IDE) will be as easy to install on that PC
as a SCSI one would be on a mac.

The discussion was never about attaching ancient CDROM's to ancient PC's. If you and the rest of MacDom would like to live in the past, that is your perogative. The rest of the world is moving past you.

>
>
>> Without more specific details, your anecdotes aren't even that.
I reiterate.

>>
>> Some people have a knack for making their lives difficult no matter
>> what they're using. Others merely don't let the machine intimidate
>> them and just follow the instructions.

>I follow(ed) the instructions, all right. Too bad they charge for the
>English translation. And any tech support. After all, if you were a
>clone maker, with razor thin margins after you gut all quality
>components out of your machine - would you want to stand behind your
>product? I would - as far behind it as possible.

Spoken like a true ignoramus. You don't have enough PC knowledge to demand money for your services.

PCdom is quite like a mine-field. There is quite a bit of legacy hardware floating around. If you go searching for it, and this is what you have to do to find it, you will get fragged. It would seem that your biases tend to lead you and your victims (customers) straight at the mines.

>I think that we will need to find out exactly how all the SPECmarks are
>generated before we can compare them in any meaningful way. I especially
>wonder why the numbers that you gave were so different from IBM's

    They weren't different from IBM's: THEY WERE IBMs.
    I gave sufficient information from my last cite that
    someone could easily verify it. My other cites were
    also similarly verifiable and all were of IBM hardware.

    There is little mystery in why more concrete, verifiable
    examples would contradict a relatively vacuous, poorly
    cited 'estimate'.

    Furthermore, an 'estimate' from IBM seems highly dubious.
    They don't need 'estimates'. They manufacture the chips,
    the machines & the OSes. They are all in production and
    can be tested directly. Estimates are simply not needed.
    I doubt that IBM would find them in any way useful.

This would be a shell level script language actually.
This was NOT the challenge.

[deletia]
>> Wrong for NT & 95, there are cards allowing you to use 4 simultaneous
>> and different monitors.
>No, No, We are talking about the OS and it's build in capabilites!

I was not aware that a Mac was capable of using multiple monitors in the absence of multiple video hardware. If this is actually the case then Apple really has innovated... '-p

Your challenge was '4 monitors'. You did not specify HOW. The challenge was met, despite your protestations.

Now, however, if you would have said that NT cannot manage to use 4 svga video cards at once, you would have a challenge that NT cannot meet.

However, that was NOT the challenge.

Need 4 monitors? Replace the video card and load the appropriate driver. This is no more than what a Mac would require. Although, with this solution, you have 3 more slots left. If the machine didn't have 4 slots to begin with, that could be mighty useful...

You said 4 MONITORS, not 4 VIDEO BOARDS.

It has the same meaning now as it did back then. It was obvious to me
what he was referring to.

>or not.

Does NT support multiple monitors? Or does a special video card and driver set? Can I take my NT workstation that I'm typing this on, and add any graphics card I want and have multiple monitors? If NT supports multiple monitors, then I shouldn't have any problems doing it should I? If you answer that I need to buy a special video card, then I don't think NT supports this...the specialized video card does.

>>Taken to literally, as things often are here. I think he was refering

>them.

Can you explain this further? I'd really like to remove all drive letters from my NT installation. I understand about the share names,that part is easy. I'm lost as to how I would access the drives from the console without any drive letters (IE, a non-networked NT system). I'd appreciate the help.

Josh

Where did I claim this?

The Mac OS can support multiple monitors on any mac where multiple
video is installed. Some macs may not allow additional video to be
installed, but if they did, the Mac OS would support it.

Actually, I believe that the value of the estimate increases due to the existance of the examples that you cited. IBM is obviously aware of the SPECmarks awarded to it's workstations so the estimate is obviosly not baseless. IBM could be compensating for the fact that xlc does not generate FMADD instructions or some aspect of their hardware that reduces the performance of the microprocessor. Tomorrow, I think that I'll ask IBM where they got their numbers.

Whatever happened to Copland? You know, the one you've been babbling about as being 'just around the corner' for the last two years....

Interesting to see how the fortunes of the Mac have slumped since you started your crap - it had 20% of the market when you first were here and now its down to 5-6% share.

Actually I just clarified (with differences in the scripting)...
someone else made the point.

If you don't understand the difference between one common open
event/scripting model, and the way windoze does it, then I suggest you
read up more... it would take too much time to enlighten you. But VBA
and MS's scripting models is not even CLOSE to what
AppleEvents/AppleScript is.

That is the kind of stuff that DOESN'T work on Windows.

It does to! If you can't create a good HAL (Hardware Abstraction
Layer) and you can't integrate the OS with the Hardware (the responsibi=
lity of the OS I might add).... then you've got a shitty System.

Also note, I didn't start that thread - I just reponded to your
response.

The PC-OS's dont do what the MacOS does BECAUSE the MacOS is more
integrated with the hardware. That is what OS's are supposed to do. I
know WHY MS has problems doing so - but that doesn't change that the
OS sucks more because it can't do what it should.

I didn't say it... I was clarifying what that person meant (or should
have said).

The point is the Mac way is still better. The Mac WILL allow multiple
monitors quite easily and cheaply. I can buy $100 video card and add a
second monitor (and on some Mac dual monitor support is built in)....
I have 3 monitors at work, and adding a second at home again (I used
to have dual). This is not achievable in the same way, nearly as well,
and at the same costs, for PC's. And once done on the PC's it doesn't
work right (the way it should) anyways.

'mom'.

Lets try this.... you can create good turn-key solutions with PC's. If a PC comes pre-set-up, and pre-configured to run one or two apps, etc... then the PC's are not bad solutions.

But if you want to actually use a computer AS a computer... to add an app, to change a configuration (without it blowing up in your face), add a card, update the system, add a printer, etc... the Mac is better. Users can understand things easier on a Mac, and more things have more predictable behaviors. Its a better computer - but as for the better solution, that depends on what you are doing. (In large companies when you have IS depts. that are paid to maintain your machines, etc. the PC is not nearly as bad as in the home).

Obligatory car analogy -

PC's are OK if used as a bus. (Someone else selects the routes and drives for you). They are great if you are a bus driver or mechanic.

But the Mac is more like a car... you can add your OWN things to it.... you can go where you want to go, when you want to get there.... and its simpler and easier to understand than the BUS's mechanicals, or even the complexity of routes, schedules, etc...

Actually the assertion was 'multiple monitors' only. There were no other restrictions given. NT can accomplish that which was stated.

Furthermore, NT can also support multiple video cards. A MacVocate would have to put extra conditions on the statement to make that impossible for NT as well. (vga+herc)

The mac examples are not nearly restrictive enough to handle the multitudes of PC variations.

>
>
>Does NT support multiple monitors? Or does a special video card and
>driver set? Can I take my NT workstation that I'm typing this on, and

'Special video card' & 'driver set' describes any video card for
either platform. (excepting PCs using vga,ega,cga or herc)

>add any graphics card I want and have multiple monitors? If NT

If that was what was originally intended, THAT is what should
have been said. Revision after refutation looks so sleazy.

>supports multiple monitors, then I shouldn't have any problems doing
>it should I? If you answer that I need to buy a special video card,
>then I don't think NT supports this...the specialized video card does.

Typical MacVocate hypocrisy:
We need to get 3 more cards and have their drivers in order
to use our solution.

But if you just buy a single card and have it's driver, that
wont count as a valid solution.

The multiple frame buffer card requires a video driver, not unlike any
other video card. In the absence of surplus hardware, the distinction
you are making is meaningless.

>lity of the OS I might add).... then you've got a shitty System.

At least some of the microsoft OSes have a HAL. That
puts them far beyond MacOS which is tied to one particular
set of hardware still executing binaries from the last
cpu family in emulation. Any RISC versions of NT are native.
That cannot be said for the 'RISC version' of MacOS.

So.. essentially... this is the MacVocate position:

Win/NT does not support features not supported by the
underlying hardware, therefore it is shitty.

MicroSloth does not have a draconian stranglehold on the BIOS
vendors. M$ has to implement over what it is given. This is
quite distinct from Apple's 'big brother' position over Mac
hardware.

That Apple could best MicroSloth under such conditions does not
do any credit whatsoever to Apple. In this case, Apple has the
same sort of 'unfair advantage' that microsoft is often accused
of.

```
       All else being equal, MacOS has no advantage in this area. MacOS
       can only claim advantage in this area when things are not equal.

       If MacOS needs such cheap propping up, then it would appear there
       is not much being propped up.

```

That is quite a different restriction.

>and at the same costs, for PC's. And once done on the PC's it doesn't
>work right (the way it should) anyways.

This is pure fabrication based entirely upon bigotry.
You have no basis for this assertion. If MacOS is so
'superior', such tactics should not be necessary.

So? How is one graphical menu significantly different from another.
Also, I wasn't merely refering to win16, either. The same could be
said of 10 year old Amigas or Atari's or Commodore's or PC's with
GEM or even a 10 year old version of X.

>
>But if you want to actually use a computer AS a computer... to add an

Just what do Mac users find so hard about hitting the return key
several times?

Also, just what configuration changes will blow up in your face?

>add a card, update the system, add a printer, etc... the Mac is

'update the system', what is this?

'Add a card' is rather vague as well. There are PC cards that are
older than any Mac (or even Lisa).

Adding a printer is quite trivial as well. If it isn't a relic,
the current revision of the OS will install it for you.

>better. Users can understand things easier on a Mac, and more things

You've yet to mention why or give some concrete examples.
Surely your 'mom' could provide us with a few. Although,
I suspect any examples will be rather dated...

>have more predictable behaviors. Its a better computer - but as for
>the better solution, that depends on what you are doing. (In large

Yes, but you've never said why (beyond csh++) in any concrete
or reproducible fashion.

I've looked at Toad's website. Yes, the prices are higher than you can get from a second-hand shop or a direct used sale. That's the nature of being a dealership--on used equipment sales, you can't compete with what somebody just dumping a machine will ask. Somebody just dumping a machine can't take your credit card and be a legal entity you can take recourse against if there's a major problem, either.

As for your statement about supply and demand, you can apply it to them just fine. Don't demand their machines and you're applying it. What's the problem there?

Nobody's asking you to be benevolent. If you think Toad's prices are too high there are other places to get the machines from. They're setting their margins, other people have their own. Personally, I think they're too high for me, so I'm counting on a sales post here to come through. But others may disagree.

I hope you don't mean this argument. You could say that about anything! My ST can't raytrace 24 bit 200x200 pictures in a few minutes but if I put a whacking great big processor in it then it could, therefore your argument says that my St is capable of of raytracing 24 bit 200x200 pictures in just minutes. It isn't, I've never heared a valid argument with a "but" in in it.

Yeah, but the Mac requires NO drivers. Put the cards in, hook up the monitors, start the Mac go to the Monitors control panel, tell the control panel where you want to put the other monitors in relation to the original (main) monitor by moving the icons around relative to the main one, set your resolutions and color bit depths, and voila! Its done dude! BTW, you can also change bit depth and resolution (on multi-sync monitors) ON THE FLY. NO REBOOTING!

Shockingly, this is a fairly recent development. For example, with
7.1 on a Centris 650, I had to grab NEC's DPI-On-The-Fly software to
do this. Amazing...

Generally drivers are required, when the board has features that are not
supported by Apples built in drivers. There are lots of drivers in the
Macintosh OS. I would print this using a printer driver. We call them
things like extensions, and control panels though.
Oh yeah, and they conflict a whole lot less often then wintel.

It's also why we PBase owners are still waiting for PCC to ship us 3D
accelerator drivers.   ;)

I think you may be missing something in the first post. He wants to
create the
script to control functions not only of an application, but also of the
OS itself.
As far as I know, OLE automation can only automate the behavior of OLE

objects which
must be exposed by an OLE Server. I don't think Windows itself is an OLE
Server -- yet anyhow(I could be
wrong here, please correct me if I am). One thing is certain though --
creating an
application which automates OLE objects isn't like making applescripts.
Certainly OLE can be
used to create very powerful data management solutions, but the learning
curve is much
steeper than the quasi-english used in applescript. VB for Apps is
pretty simple to use for OLE work,
but you still have to have some concept of methods, properties,
objects...

Can one use OLE Automation to shut down a Win95/NT PC?

Mark

Right no drivers whatsoever. That's why the guys at Matrox wasted all
that time writing a driver for the Millennium on the PCI PMacs.

I'm not sure what the distinction here is.
Any OLE Server can be manipulated. Every component, application, control, whatever that is registered in the HKEY_LOCAL_MACHINE\SOFTWARE\Classes is an OLE Server and can be manipulated--including the shell (in this case Explorer).

If you mean using OLE to manipulate the kernel level objects directly, you're right, I can't. I'm not so sure you can do the same with AppleScript. You're right that only registered OLE servers can be manipulated. However, I think you underestimate the depth and breadth of OLE servers on a typical system. I would quite surprised if there was somethng you could with AppleScript that I couldn't do with OLE automation.

>...but the learning curve is much
>steeper than the quasi-english used in applescript. VB for Apps is
>pretty simple to use for OLE work, but you still have to have some
>concept of methods, properties, objects...

VBA is one of the languages you can use for OLE automation. REXX is another. Perl, is I believe another (although, it has trouble with OLE servers contained in .DLLs instead of .EXEs)

As to the learning curve, yes OLE automation is harder. However, I would argue that OLE automation is also more functional.

>Can one use OLE Automation to shut down a Win95/NT PC?

Now wouldn't that be a nasty trick... :-)

Yes, it only requires an OLE server which has the functionality. You can create a program that will issue a InitiateSystemShutdown() and export that method. With MSVC, you can do this with about four lines of code (the framework can be created using MSVC's AppWizard). Build it, run it once, and you'll have it registered for any OLE automation "client" to manipulate the program.

Infact, I wouldn't be surprised if you could manipulate the Explorer shell itself to initiate the shutdown.

I wouldn't go so far as to call them "drivers", at least not in the Intel sense. The Mac has a fairly strictly defined video spec. Any monitor board which adheres to that spec simply works. Now, of course it is true that if certain boards have special features not supported by the Mac system (for instance, for years Raster-Ops had a feature which allowed you to zoom in on the screen with some keystrokes) then they needed to include an extension or control panel to enable those features. Keep in mind that the board would work just fine without the extension, it just wouldn't be able to access the special features. Wintel machines, OTOH, need a driver for each board at each resolution and at each color bit depth. In other words, compared with the Mac, its a mess.

Then they are idiots. I have NEVER seen or used any Nu-bus, PDS, or PCI video cards on the Mac which require any software (other than the what is inherent in the OS) to run them. They are plug-and-play in the purest sense of the word.

Which is why Conflict Catcher is among the Mac's hottest selling software? Not to mention the extension manager in Now Utilities, or the extension manager built into new versions of the MacOS. Or how many times Mac users have advised other Mac users to solve crashing problems by eliminating extensions one at a time.

On the other hand, I've never even seen a driver "conflict" on a Wintel machine. Please elaborate.

No, it's more like running your graphics board under Win in plain VGA mode. The Mac is always in basic mode; it doesn't use things like polygon fill, even if the graphics board can do them. Arguably, that stuff belongs in a coprocessor, like the QuickDraw 3D accelerator, rather than in the graphics board, but Apple has been notorious for building machines with sockets for wierd kinds of video coprocessors and not building anything to put in them. (If you have an "AV" machine, you know about this.)

I'll respond for David on this one. What he is say is that you CAN
expect all the screen to be doing something different from one another.
As for having much use, try this one: Imagine having a Photoshop image
displayed on a 20 inch monitor at 24-bit color depth while all those
otherwise annoying floating menus that Photoshop loves to display are
all by themselves on a second 17 inch monitor running at 16 bit color
depth.
True there's lots of mousing around necessary, but it's worth it for the
extra real estate.

Kurt

<<No, No, We are talking about the OS and it's build in capabilites!>>

If you could write a driver for using 4 monitors, The OS supports it.
NT's driver model and graphics interface supports it out of the box.

Right, *they* are idiots.
In that case, so are the groups from ATI, Ascend, and IOmega among
others. Because each of those companies have Mac devices which
require a driver.

>I have NEVER seen or used any Nu-bus, PDS, or PCI
>video cards on the Mac which require any software (other than the what
>is inherent in the OS) to run them.

And since you've never seen them, they therefore do not exist or if
they do, the people making the devices are idiots. Great line of
logic.

Because like Conflict Catcher, uninstallers address a very real
weakness of MS Windows.

Just like Conflict Catcher, you have RAM Doubler--addressing a real
limitation of MacOS. And on the Windows side, you have dozens of
shell "enhancements" (ala, PC Tools, Norton Desktop, DashBoard,
etc...).

>>On the other hand, I've never even seen a driver "conflict" on a
>>Wintel machine. Please elaborate.
>
>Then you haven't been using PCs very long.

Sorry, there is rarely a driver conflict. Drivers do not stomp on
each other--simply because it's awful hard to shove two video drivers
into the same machine at the same time. What does happen is that

drivers are either buggy or the hardware isn't supported.

THESE numbers would suggest otherwise.

/**/
[file edited for brevity]

SPECmarks for various machines

$Id: spectable,v 5.92 1996/12/05 14:58:41 jdd Exp $

What this is: A file of reported SPEC CINT/CFP benchmark results (means only) for various machines. These figures are generally taken from numbers published on the net, or in manufacturer press releases or reports.

This file is organized into eight tables, the first reporting SPECint_base95 and SPECfp_base95, the second reporting reporting SPECint_rate_base95 and SPECfp_rate_base95, the third reporting SPECint95 and SPECfp95, the fourth reporting SPECint_rate95 and SPECfp_rate95, the fifth reporting SPECint_base92 and SPECfp_base92, the sixth reporting SPECint_rate_base92 and SPECfp_rate_base92, the seventh reporting SPECint92 and SPECFP92, and the eighth reporting SPECint_rate92 and SPECfp_rate92. SPECmark89 (obsolete) is no longer reported.

There are no chip-only entries (as opposed to systems with those chips in them); SPEC CINT95/CINT92 CFP95/CFP92 are suites of component-level benchmarks that measure primarily the performance of a system's processor, memory architecture, operating system and compiler. Reporting SPEC results for a chip alone is misleading.

Some specrate numbers have been computed from reported specint/FP92 numbers for various uniprocessor systems. These are indicated by a trailing "c".

Manufacturer estimates, or estimates of any sort, are not normally reported.

This file is available via anonymous ftp from ftp.cdf.toronto.edu in the file /pub/spectable.

A SPEC FAQ describing the SPEC benchmark suite and the SPEC consortium is periodically posted to comp.benchmarks, and can be found on the WWW at "http://www.specbench.org/spec/specfaq.html". I strongly recommend reading that document before using these numbers.

More SPEC-related information is available at the SPEC WWW site, "http://www.specbench.org", and at the Performance Database Web site, "http://performance.netlib.org/performance/html/spec.html".

Note carefully: benchmark results depend not only on processor type, speed, and cache size, but compiler, OS and other machine characteristics that are not reported here. In particular, the compiler can have a significant effect.

Quote:

> " While no one benchmark can fully characterize overall system performance, the results of a variety of realistic benchmarks can give valuable insight into expected real performance. "
>
> - SPEC newsletter.

Disclaimer: These numbers have not been verified. Nobody guarantees their correctness, and there is no guarantee that they accurately reflect the true performance of these systems. Furthermore, this is not a publication of the SPEC consortium and is not endorsed by the SPEC consortium in any way.

Please send all corrections, updates, and new entries to jdd@cdf.toronto.edu.

I suspect they're trying to liquidate their remaining inventory without
too much of a loss.   Now that they're in the PC business, all that old
ST equipment is taking up room and costing money to store, heat, and
air-condition. If you mention prices, they'll probably come down.

I thought STeve Kipker's STeve's Atari Sales was the last Atari-only
bastion, but even STeve has been forced to go Macintosh. But he hasn't
made the intimations that he is dropping TOS support (like Toad has).

> Toad's prices for used ST equipment are way too high, IMO.

We set our prices based on two basic principles: supply and demand. In our experience the prices on that equipment are agreeable to the people who buy it, hence their inclination to purchase.

With all due respect if you would like us to lower our prices, you will need to either increase supply or decrease demand. :)

They do suggest otherwise but I got this from www.ibm.com:

Performance (estimated) 6.7 SPECint95, 6.3 SPECfp95 @ 166/66, 1M L2

It is interesting that this indicates almost 25% better floating point performance with 83% of the clock speed. I couldn't find numbers for a 166MHz 603e so:

Performance (est) 5.6 SPECint95, 4.1 SPECfp95 @ 200/66, 1M L2 SDRAM

and, reducing everything by 87% (which is actually an exaggeration since microprocessor performance does not increase linearly with clock speed):

4.6 SPECint95 3.6 SPECfp95

Do you know if the PPC chips are required to operate in an accordance with IEEE-754 during SPEC testing? That would cost them a few fractions of a point and some precision.

I'd give it least 5 years.
Look at the large number of dead operating systems that still have
groups:

Amiga ( company bankrupt )
Atari ( company bankrupt )
desqview ( abandoned by quarterdeck )
coherent ( company bankrupt )
Plan 9 ( abandoned by AT&T for Lucent )

The only newsgroup that looks positively ill is the coherent
newsgroup. However, Mark Williams ( the original coh company ) went
bankrupt  _many_  years ago.

I used Macs some years ago.
I looked at them again recently (I use Linux, Win NT and Win 95)
A couple of my secretaries use Macs.

I am amazed that the Mac OS still doesnt have preemptive multitasking.
I am amazed that the Mac OS still doesnt have robust security.
I am amazed that the Mac OS still doesnt have robust process memory space isolation.
I am amazed that the Mac OS still doesnt have decent background high speed comms.

These things have been taken for granted in most modern oses for years !

It is a tremendous Mitzvah to always be happy!

You bet that comp.os.os2.advocacy will be around! I understand that there are still several hundred members of the Flat Earth Society as well.

At least this escapade has taught me, for one, never to trust IBM again. Customer abandonment once is sufficient, thank you.

: Toad's prices for used ST equipment are way too high, IMO. Last week, an
: Atari dealer offered me a NEW FALCON for $300 (albeit 1MB, no HD).
: Compare this with the $299 "special" Toad is offering on USED STe's.

I agree Toad has High prices.

: Also, a few days ago on this very group someone was selling a VERY nice TT
: for $300. I think people in this group ought to write to Toad and tell
: them that we are not willing to pay these prices!

Why should I? I vote with my pocket book. I am not willing to pay those prices, so I wont. Toad loses a customer. They have a right to ask whatever they want for their Atari stuff.

: I know that Toad has
: long supported the Atari platform, but that is not an excuse to excercise
: price gouging. If you agree, write to Toad "Toaday" and let them know
: their prices are way off. I think the Atari community will be better off
: with realistic prices set for equipment.

I agree here. The Atari community should have realistic prices. Toad doesn't have those realistic prices, so buy used. I have never understood how Toad became THE name in Atari. I wont buy from 'em.

I am amazed that Windows (NT, 95, CE) doesn't have scriptable applications
I am amazed that Windows (NT, 95, CE) can't boot from a removable SCSI disk
I am amazed that Windows (NT, 95, CE) can't use 4 monitors at once
I am amazed that Windows (NT, 95, CE) can't be booted out of RAM
I am amazed that Windows (NT, 95, CE) can't be used by my mom
I am amazed that Windows (NT, 95, CE) still have lame alias architectures
I am amazed that Windows (NT, 95, CE) are still limited to C: and D: drives

You know man, what you just wrote is common knowledge in the Macintosh world. Still why do people prefer the MacOS? Because it works, and damn good as well, I see Linux systems, NT systems and although I have to admit NT 4.0 is not far off anymore, I am stil frustrated all over the place when I try to do the same things on a PPro machine with NT that I pull off with my humble little 601 PowerMac.

>a 166MHz 603e so:
>
>Performance (est) 5.6 SPECint95, 4.1 SPECfp95 @ 200/66, 1M L2 SDRAM

       These numbers are wholely imagingary. An 'estimate' and an
       'estimate' based on another 'estimate' are about worthless.
       Couldn't you find any ACTUAL specmarks. IBM's page may be dog
       slow & the java search engine may be crap but, their workstation
       specs (real ones) are not at all hard to find...

What are we measuring here? The performance of the chip or the performance
of a workstation that uses that chip? You were the one who suggested that
the processor should be tested without including memory systems, etc.

Let's deal with the security issue. Who won the contest to see if any
hacker could break in to a Mac server and bring it down? Since you say
Mac's have no security of course.

So.  Did IBM actually publicly abandon OS/2 or is this just whining?  Could
some one direct me to the official announcement?  I thinking about getting
Merlin in a couple weeks and if IBM officially dropped support I may reconsider.
I was really excited about a PPC version of OS/2 and was disappointed when IBM
dropped that.  Since I can't afford another computer, and no CHRP or PREP hardware
is available, that wasn't a real problem but if they are quiting on the INTEL
version, that's definately more serious.

Wrong.

>I am amazed that Windows (NT, 95, CE) can't boot from a removable SCSI disk

Wrong.

>I am amazed that Windows (NT, 95, CE) can't use 4 monitors at once

Wrong.

>I am amazed that Windows (NT, 95, CE) can't be booted out of RAM

What does this mean?

>I am amazed that Windows (NT, 95, CE) can't be used by my mom

Can't comment since I have no idea of what your mom is capable of, on the other hand, I would give her the benefit of the doubt, you however do not feel the same.

>I am amazed that Windows (NT, 95, CE) still have lame alias architectures

Alias?

>I am amazed that Windows (NT, 95, CE) are still limited to C: and D: drives

Wrong again.

Amazing, with all the real shortcomings with Windows NT, you've managed to miss every single one of them.

No, as of yet IBM has not officially dropped support for OS/2. There is hotly-contested speculation that IBM is attempting to let OS/2 die a slow death rather than execute it with a single blow.

Note that *everything* which I will say here is highly controversial. The actual amount of uncontested facts available is damned small; what there are is rumors and rumors of rumors. So virtually everything I'm about to repeat could be either true or false. I am not, at least in this article, trying to make a statement; rather I'm making a quick attempt to summarize the best cases both for and against the contention that IBM is letting OS/2 wither. (And *every* one of these statements can be spun multiple ways, too.)

The case FOR IBM letting OS/2 wither:
1. The development budget for OS/2 has been dropping for some time, and there seems to be reason to believe that it will continue to drop.
2. Presence of OS/2 software in store-front retail outlets has gone from small to nonexistent in the last year, and IBM has not made any attempt to do anything about it.
3. IBM has announced that the target for OS/2 is business. High IBM officials have made disparaging comments about the home market as a target for OS/2. They occasionally toss in comments about "connected consumers" as a target, but that may simply be lip-service.
4. IBM seems to not be making much of an effort to cultivate support among 3rd party developers, either of hardware or software.
5. In the first half of 1996, sales of OS/2 were termed "disappointing" by IBM. Unofficially, they apparently sold about 1 million copies in the first 5 months of 1996.
6. IBM tends to announce sales figures when they're good; IBM has

announced no sales figures for Merlin (Warp 4). In this case, "no news is bad news" and reading between those non-existant lines it is likely that sales of Merlin have also not been good.
7. The supply of native applications for OS/2 continues to be disappointing.
8. Support for OS/2 elsewhere within IBM is something between laughable and non-existent. Especially IBM PCCo, which is probably the one division that PSP would most like support from, has basically abandoned OS/2 and spends all its time pushing Win 95 and Win NT.
9. Advertising by IBM for OS/2 has been sparse and unimpressive.
10. The last major monthly OS/2 magazine in the US just stopped publishing, primarily due to lack of advertising.

The case AGAINST IBM letting OS/2 wither:
1. IBM has formally stated several times recently that it is their policy to support and enhance OS/2.
2. IBM made a special deal with Netscape to port Navigator to OS/2, and IBM is giving it away for free. Though the details of the deal have not been made public, it is assumed that IBM paid Netscape a pile of money for this. Clearly this is a major investment.
3. About a year ago IBM spent an enormous amount of money moving people from Florida to Texas so as to consolidate the development for OS/2 at a single site. That would seem to be unlikely if they wanted to abandon the very product those people were working on.
4. IBM's Lotus division recently announced that they had contracted with an outside developer to port some of their major packages to OS/2.
5. While the supply of native OS/2 apps is nothing like as big as the supply of Win16 apps, it is still comparable to the supply of WIN32 apps, and OS/2 can run most Win16 apps anyway. Just how many spreadsheets do you need? (As they say, "More than a mouthful is a waste.")
6. The features of Merlin are the best of any version of OS/2 to date. The user interface has been upgraded, and voice-controlled navigation and dictation have been included at no extra cost. Even better, it is highly integrated with the desktop and permits easy control of the whole interface.
7. The OS/2 user community is highly connected, and electronic commerce for OS/2 software is alive and healthy. Indelible Blue can sell you anything you need, easily and rapidly, so who needs store-front presence anyway?
8. Equally, while the paper magazine may have gone under, there are several quite good e-zines about OS/2 and they are doing fine. [Although one of them let some asshole Win 95 advocate write a column for a while, but fortunately he gave up and quit.]
9. People have been saying "OS/2 is doomed" for years, yet here it is, going strong.

So there you have it. I've probably missed some points, but these are most of the important arguments which have been tossed around by people on both sides.

I think I can make the following statements without fear of
contradiction from anyone:

1. IBM is, as they always have, doing a less than sterling job of
marketing OS/2.
2. IBM is not investing as much money in OS/2 as advocates wish they
would.
3. 3rd party support for OS/2 is not as good as OS/2 advocates wish it
was.
4. The signals from IBM as a whole have been ambiguous.

Absolutely not. IBM has stated they will continue to support OS/2. This thread is more speculation than anything else, so make of it what you will. I personaly believe IBM is working to bring together a more solid strategy around OS/2 -- they recently stated they were working on tying OS/2 in with their Network Computer initiative. Others may scoff, but they have no real proof (other than their own personal reading of the leaves). I may be reading in as well, but *no one* has final word on what is happening right now -- it's all based on action or nonactions by IBM, but *no* official announcements have been made.

<snip>

Interesting post, and refreshingly unbiased. I like to think that IBM is working to come up with a fresh strategy for OS/2, based around Java and the NC initiative. It could be wishful thinking, but no one can tell me for certain that it is or is not true.

It *is* frustrating that IBM can't come up with a more coordinated effort with OS/2 -- what's so difficult about making the PC Co and PSP work together on creating a good preload package for the Aptivas? Why can't IBM get a good OS/2 suite out the door? Why can't they bundle new software and package them more attractively? Netscape's and Stardock's efforts are the best initiatives I've seen in this direction; why can't IBM take a cue from these vendors and market their own stuff this way? These are simple things that don't cost huge sums of money, and could make all the difference in dispelling the "OS/2 is dead" stories.

Unfortunately, the longer IBM waits to address these issues, the more creedence is given to the rumors, and the harder it will be to revive OS/2 later on.

Very nicely done post! I don't know why people are so concerned about
the future of OS/2, from the standpoint of IBM's support. Heck, we have
each other, and the operating system itself, won't go anywhere, right. I
use, and will continue to use OS/2 Warp now and for the next umpteen
years. I'm certain it will run most of the programs I will ever want to
use; so why should I worry if another version of OS/2 isn't made.

Use it, be happy, and support oneanother. Let's face it, if we don't
help each other, then than is when, and only when, OS/2 is really

doomed.

Actually, with MS's Dfs I can move the app anywhere and the mount point doesn't have to change as far as the client side is concerned. In otherwords, \\tango\tmp can point to anywhere and can be changed on the Dfs server without having to have the client remap it.

>And what's that "G:" doing up there?

If you mean "H:", it's the default location where the shell starts up from (since that's where it's located). I can have it point to \\tango\tmp if I wanted to (by setting the startup directory in it's shortcut). I just didn't bother since the poster just wanted me to show him that NT is not limited to drive letters.

Ok, can I write a script within the OS that opens Word, opens a document, prints certain areas of it, quits Word, copies the file to the server and shuts down the computer?
No I don't think so.

NT certainly can't do it, starts to complain about the unability to run 16 bits apps and you can't open a DOS box, but a CMD box works.
thus right!

Umm, guess again.
Using OLE automation you most certain can do what you describe.
Infact, using OLE automation, I've been doing what you describe (and
helluva lot more) for the last four to five months.

>> <<I am amazed that Windows (NT, 95, CE) can't boot from a removable

What are you talking about?
NT can be made to boot from a removable device. And why would booting
NT from a removable media affect the NTVDM?

>> <<I am amazed that Windows (NT, 95, CE) can't use 4 monitors at once>>
>>
>> Wrong for NT & 95, there are cards allowing you to use 4 simultaneous

>No, No, We are talking about the OS and it's build in capabilites!

No, No, read the statement:

"I am amazed that Windows (NT, 95, CE) can't use 4 monitors at once"

I don't see "built in" capabilities anywhere in that statement. The
fact is NT can support multiple monitors. Now you just want to change
the criteria since the first statement was proven to be false.

So...you have "long drive letters". If you have an app on tango and move it to mango, things break if the app has stored it's path somewhere. You can't just remount mango to the mount point that tango was on and have everything still work, nor can you make a symbolic link to the new spot, right?

And what's that "G:" doing up there?

Get Microsoft's update.   I want to call it DFS, but I'm sure when Sang gets back he can tell you more. It abstracts location of files on the server from the clients. Quite nice.

Since this was hashed about a few months ago, his meaning was obvious to me. Simply put, the Mac OS can use multiple monitors without the need for specialized cards to do so. He's correct in his original assertion, your changing it to suit your needs.

Taken to literally, as things often are here. I think he was refering to drive letters in general, not specifically "C" and "D". Drive letters are one of the few things I do not like about NT.

Since that was a few months ago, the context isn't the same. That should be obvious to you.

>Simply put, the Mac OS can use multiple monitors without the

>assertion, your changing it to suit your needs.

Since when?
The original assertion was that NT can't support multiple monitors.
There was absolutely nothing about whether that support was "built in" or not.

The latter only came up after the *original* assertion was proven false.

Look above carefully. Drive letter are there simply for compatiblity reasons. You do not have to use them nor are they even required. Infact, you can use disk admin to remove every single drive letter from all your partitions--using just their lables/shares to access them.

Who are you going to trust instead, Microsoft? They're the ones who abandoned OS/2 in the first place, remember? The bottom line is that you can't trust *any* of these guys, so don't fool yourself.

Trust in Linux - it'll be around as long as there is someone who will
maintain the code.

NT seems to be good ride right now, too.

>I am amazed that Windows (NT, 95, CE) doesn't have scriptable applications

You haven't been looking very hard or are just lying? Word and Excel
are so scriptable they have their own virii.

>I am amazed that Windows (NT, 95, CE) can't boot from a removable SCSI disk

This depends entirely dependent on the BIOS, not the OS.

>I am amazed that Windows (NT, 95, CE) can't use 4 monitors at once

This is also WRONG. Troll around the STB homepage. The PC solution
is different.

>I am amazed that Windows (NT, 95, CE) can't be booted out of RAM

I think that the Atari ST/TT/Falcon would be the only ones
capable of this feat. MacOS was never small enough to manage this.

>I am amazed that Windows (NT, 95, CE) can't be used by my mom

Perhaps my mom should teach your mom.

>I am amazed that Windows (NT, 95, CE) still have lame alias architectures
>I am amazed that Windows (NT, 95, CE) are still limited to C: and D: drives

>
>What are we measuring here? The performance of the chip or the performance of a workstation that uses that chip? You were the one who suggested that the processor should be tested without including memory systems, etc.

It is a practical impossibility to completely isolate a microprocessor from it's attached hardware. It requires that attached hardware to do any work.

I suggested that statistical skewing due to factors outside of the microprocessor be minimized. Other variable factors within the respective machines should me made as equal as possible. Ideally, one machine capable of using either processor as the main cpu would be most appropriate. Short of that, the machines should at least have equivalent features. Everything outside of the CPU should be as close to identical between the machines as possible.

Otherwise, it's nothing resembling a CPU benchmark anymore.

The results may be able to say something but: it won't be
cpu X is faster than cpu Y.

Of course allowances can be made for architecture features that are simply not present on one cpu or the other.

Either way, 'estimates' are still worthless.

I most probably won't, probably get a UMAX Apus Tower.

>Quality and pricing of apps compared to TOS ones is not good? Please list the
>apps and prices compared to the equivelant TOS ones..

No I'm sorry Pete, the programs may have more features and all the
stuff you list as usual but pound for pound they aren't as good value,
I don't want to pay for features that I don't want. Some of the fun
and very lightweight apps are well priced but go for Word/Excel and
that's 250UKP each, Pagemaker 400UKP, Photoshop 400UKP. These prices
are all well and good if it's the core of your buisiness but if you
think I'm going to spend 800UKP(+VAT!) to do a bit of image
manipulation and design my web pages then you are quite wrong.

>> Which

Self modifying code is very expensive in most cached architectures (especially
ones with split cache) so it is very reasonable to exclude it from the
PEF.

This is true, except for the $30.00 more per app at Walmart. My statement was, "Go to Walmart and try to purchase some Mac software on a Friday night binge. Good luck." Sometimes I like to go shopping with my family, and sometimes we end up at WalMart or the Wherehouse. Been a while since i've seen Mac apps there. I wasn't talking about a "planned" purchase. My budget dosen't require me to "plan ahead". If i'm out at 10:00 pm and see something I "want" I buy it. As far as the superstores go, very rarely do they beat the "Zones" prices, but it is funny to see all the Mac's piled up in a little corner with three or four models being shown when 3/4's the store is full of the latest PC crap and the other 3/16 full of PC software and add on's. That leaves about 1/16 for the Mac market. Yea, I get the glossies weekly at work where my Uncle buys everything I want out of it:) If I don't like it, I give it away. Spoiled bastard, arn't I:). I'll bet it drives you insane that a 1986 1040STF with a VideoMaster is used to inspect mirrors for weapons in use by the U.S.....well, lets leave that part out. The 1040 fits nicely under the Zygo and didn't cost our lab but about $150.00 in hardware.

Do it again. Peter.

>

Spoken like a Gentleman. Well said. I totally agree there are some
awsome products for the Mac that will never be matched in the TOS
market. However, there are some TOS apps that just can't be passed
over, as most current and ex-TOS users know.

> > resolved after discontinuation.

No problems here. It's a very nice machine for the price, and is a
complete
package not needing a fist full of cash to get it started. You can
actually
start out with just MagiC Mac, decide which TOS programs to keep and
which
to replace and go from there.
If you have the cash to blow, get an SGI.

> >

But not for the hardware add on's. They will remain expensive long after
the
machine is considered outdated.

> >
> > Where selling the Performa 6400/180 for under $1500..

> >
> I grabbed my Performa 6320 (120 MHz 603e) for $1500 at Staples, including monitor, KB (oooh, they even gave me a keyboard! :')), mouse (whoohoo! a mouse! how generous! ;'>) and a load of CDs with a lot of crappy software and some decent stuff.

Kind of high for a slow Mac isn't it? Indeed, Sinplop has stated this many times over. Not once does he compair the 120mhz to the Falcon or Hades, it's always the 220mhz 603e or the beastly 604e. Can you image? Why even compair a 180mhz 603e to the Falcon. It's just plain stupid and a method to keep threads like this going. We are talking about a 16mhz 030 machine here are we not? But as slow as it is, like the action on a 44 mag, some prefer it to what else it out there.

>
> I am running SoftWindoze 95, which is competent, and a tad faster here than on some friends' 486/66 DX2s. I plan to get MagicMac, so I can continue running some of the better TOS apps (like Calamus SL). Purchasing a replacement for Calamus on the Mac platform would set me back over $700, something I'm not too keen on right now.

Now there is a honest, truthful statement that makes sence:)

>
> Really, it's not as bad as JEDI infers, nor as blissful as PSD proclaims.

Isn't that what this is all about?

Mike

New version of NoCrew's MPEG Audio Layer II realtime DSP player for Falcon
is out now!!

Latest version is 0.95 with lots of new features from the last one. (0.7)

* Dynamic buffer allocation
* Config file
* Drag & Drop protocol supported
* VA_START message supported
* Keyboard control
* Automatically find the next song
* New buttons:
  * Skip to next
  * Skip to previous
  * Fast Forward
  * Count direction

Read more about this product on http://noring.org/mp2 where you also can get the latest version. It can also be found on ftp site:
ftp://ftp.nocrew.pp.se/pub/nocrew/tos

Download, unpack and blast away with your mp2 songs playing in the background, taking no CPU time!

Mpeg songs can be found at http://www.iuma.com or ftp://ftp.iuma.com

!!!!!!!!!!!!! NOTE !!!!!!!!!!!!
ONLY STEREO SONGS ARE SUPPORTED

Let's hear now what the public has to say about this.

Anders Eriksson, aka Evl of DHS: "BLOODY WELL DONE!!"

I'm not sure if he was talking about the player or his dinner though.

This is a dream coming true for every Falcon user, try it now!!
Send donations afterwards! :)

Tomas

Not the original version which fit in the 64K ROMs of the Mac 128.

>>Are you kidding? Basic TOS has *no* memory management, or at least not

>>RAM in the machine. (We were talking about what fits in 200K, remember?)
>
>So why are you mentioning Quickdraw, then?

QuickDraw has been around since the beginning. Its feature set beat GEM then. The major thing missing was full color support (in the era of the B&W Macs, QD supported an 8-color scheme that was never really used). But in a graphics API, color support on the level of setting a color to draw in is trivial to implement. And that's basically what GEM has.

>>MultiTOS was crap. I say that from experience. :)

Would you say the same of Linux? I've got a benchmark that runs faster under MacOS than under Linux, on the same Mac. And no, it wasn't built to do that.

>
>An AES is no extension, it's an elementary part of GEM.

Did you or did you not read what I was saying? TOS = what's in ROM. N.AES is replacement for MultiTOS AES, which in turn is a replacement for the ROM AES.

>>The original message said
>>something to the effect that TOS was better than MacOS because it was

>>were due to the extremely spartan nature of TOS.
>

```
>Nope, they are due to the portability and easy improveability.

And where does the portability and improvability come from?  Mainly from
the fact that the base TOS system is, as I have been trying to say all
along despite your continual sidetracking, a very simple and spartan OS.
The simpler they are, the easier they are to port and improve upon.  Is it
too difficult for you to understand that I am not trying to argue anything
else?

>>Yeah, and it was new in 1984.  I'm pretty sure HFS got introduced by the
>>time the Atari came out.  (I think it's obviously no argument that HFS
>>blows away the FAT file system used by TOS.)
>
>And HFS is blown away by MinixFS.

Sorry to break it to you, but it simply is not.  MinixFS is a simple
i-node file system, which, while much better than FAT file systems, is not
too hard to beat.

Let me give you an example.  On the four partitions I have mounted on my
Mac desktop right now, there are roughly 9,500 files.  If I try a find
file on a phrase that doesn't exist in any of the filenames on any drive,
it finishes with no matches found in about 1.5 seconds.  That's for
searching the entire directory structure of each drive.  I very much doubt
any inode file system could do the same.

I've not even heared of IRIX but from what I have heared BeOS is a
superb bit of kit and if I get a Mac I will be only to happy to
install the PowerMac version when it is released. The problem with
MacOS & Windows is the need to retain backwards compatability to the
very earliest of machines, with BeOS they have a brand new OS written
for the new hardware. It's taken the modern good bits of MacOS and
mixed them with the simplicity and power/efficiency of TOS, making an
OS that is just right.

>Yup, no self modifying code :(

You can't have it anyway. Self-mod is a no-no on any CPU with split instruction and data caches, whether it's the 68040 or PowerPC 604e. (You can write self modifying code on the 601, because it uses a single unified cache, but it will break hard on the other PowerPC processors. Not recommended.)

The lone exception to that rule is probably the x86. Intel spends extra silicon to allow even the P6 to execute self modifying code correctly, without any forced cache flushes. They probably did this solely because of the pressure to maintain full compatability with really old DOS programs, etc.

I have 6 partitions on my 4 meg/TOS 4.04 Atari Falcon...that equals 492
folders and 5,427 files...using the standard, drop-down search option
from the menu bar, I can do the same search with results in around 2
seconds... :)

> I have been using Atari products for many years. When I was a teenager, a friend had an Atari 800 and I was very impressed with it. I also got an Atari 800 and learned to program a bit on it, played some games, typed in programs, etc. I lost interest in computers for a few years after that. Once I was in college, I started writing a lot and was using an Apple IIe with AppleWorks as my writing tool. I remembered using an Atari several years earlier and looked into getting one again. I would up getting a 130XE with disk drive and Atari Writer Plus and was pleased with the performance, even though I only had 40 columns in my word processor.
>
> Sometime later I found out Atari was still making computers and I bought a used 520ST. I was amazed with the usefulness of the machine. I loved using NeoChrome to draw pictures (an application I hadn't really tried with a computer before). I also started to delve into a little BASIC programming and was very satisfied with the machine. I upgraded to a 1040STe later to run Calamus. I liked Calamus a lot and used it to produce all kind of things at work from bookmarks to flyers to invitations, etc. I then went to an Atari show and bought a Falcon. In the two years I had this machine I started writing reviews of software, using a lot of PD and enjoyed the graphic applications of the machine.
>
> I also bought a Jaguar when it came out (not that I was a big video game player - actually I never had played video games all that much). I was impressed with the system, though, and hoped it would be a sucess.

> Thomas Main
> main@appstate.edu
> -----------------

Hi Thomas,

I currently own two Atari machines, a 1040STE and a Falcon. They are both very good machines, but Atari have really left users to fend for themselves. Fortunately, other companies have taken over where Atari left off. There are a few Atari clones around, such as the C-Lab Falcon I, II and MK-X, the Direct TT040, 060, Medusa040, 060 and the Hades. There is even a new machine being developed in France.

Although the Computer market is hardly flooding with Atari Software there is a good supply of quality software, both commercial and shareware.

It seems that as one more company abandons the Atari market and makes me re-think whether or not I should continue with Atari, another Company takes its place.

I hope to stick with Atari as long as I can. I don't wan't to have to switch to a PC running crappy Windows, which takes so much processing power to run, you need at least a Pentium before you've even started.

Anyway, enough of my rambling.

Cheereo,

Ben Hills.

Can you see a little bit of GEM in the BE GUI? If so, then that would be
great! And, if so where would I get to see the thing?

I always hated that the Mac was a "GUI by committee" with Jobs breathing
down the committee's neck to "get it finished". GEM was the vision of one
person, Gary Kildale and shines because of it!

Ah, now I see. You are using "simple and spartan" in the meaning of "slim and resource friendly". Sorry, my mistake. Seems I need to brush up my English a little.

>The simpler they are, the easier they are to port and improve upon.

The fatter and crappier in source they are, the less. Tells one about MacOS when one reads the estimated release date of System 8.

>>And HFS is blown away by MinixFS.
>
>Sorry to break it to you, but it simply is not.

Copying a file on MacOS lasts significantly longer than on any other FS, including the original TOS-FS, e.g..

Thorsten

Either they don't know how bad they have it, and we do, or they just
don't get it. Can you image all these big bad Applets picking on our
little platform. Why can't we just die in peace:)

Mike

New Atari applications _certainly_ do! And by new applications I mean app's from 1991/92 so forth.

And Atari's have pre-emtive multitasking OS, namely MagiC and the very powerfull MiNT+MiNTnet+N.AES which has support for BSD sockets and built-in _true_ TCP/IP network at OS level thanx to MiNT-Net which is a socket.

Things which MacOS doesn't have!

......And will never get either, since Apple has cancelled the development
of CopeLand, the "next generation" MacOS that was suppossed to be pre-emtive.

> There have been previous Mac apps that failed the guidelines and as a result
> failed in the market..

Just as MacOS has now, and Apple seems to admit it by cancelling the CopeLand
projekt!

Of course there's always BeOS, which has been ported for Mac hardware, but
it is by no means compatible with MacOS software.

Keep Cool and Flying...

Dear Portfolio friend,
i hope you can answer me:
Can I change the ram cipset in my portfolio for more internal ram ?
Where I found a serial port for my portfolio ?
If yes How ?
Can you send me material about portfolio big write?
Have you the ATARI PORTFOLIO's electric map ?
I LOVE PORTFOLIO and I wount all material about it
I hope you answer me soon.

A Friend

Since disk access is handled in server code rather than in kernal code, the kernal of the particular linux flavor doesn't matter if we assume that the server makes little use of the kernal. This is the case. Of course the loading of the kernal from disk at bootup is done in kernal space.

being an avid amiga user, and being a perso who has used just about everthing
out there as far as OS's go... i wonder what is the benefits of using TOS?

I am not being sarcastic, or anything like that. I had a friend who used to
use an atari, and he loved it. But he had gotten rid of it before i ever
got to see anything from it.

So give me some idea of what TOS is about. Also, what does TOS stand for??
(??? Operating System)

thanks guys... maybe one day the world wil wise up and abandon M$ winBloze!

I know that some of you have this machine gathering dust in a closet. Your probably using a Mac or a PC now and didn't think anyone would ever want to buy your ST. Well, here's your chance. It's not worth much but at least you'll get something for it.

I'll give you $100

TOS stands for "Tramiel Operating System" or "The Operating System". Take your pick. It is similar to other operating systems. "TOS controls the way the computer works, handling tasks such as reading from and writing to disks, translating mouse movement into onscreen cursor movement, and displaying information on the screen." - from the MegaSTE manual.

GEM is part of TOS (also from the manual!). It was written by Gary Kildall and team at Digital Research Inc. (DRI) and recoded to work as the GUI (under TOS) for the ST line of computers. GEM was originally written as a GUI for the PC (I am told and I really don't know why it wasn't successfull in that regard.) Gary Kildall passed away last year. GEM is (IMHO) the very best of all the office analogy GUI's as it was written with one persons vision (Gary Kildall) and it really looks just like a simple office. It originally had icons for file drawers, folders, files and trash cans and directories would list out on virtual sheets of paper. Why MS called them windows I have no idea. Windows have nothing to do with an office. Double click to run programs - how easy can you get.

Atari did very well to go to DRI for their GUI instead of writing it "in house" (although they probably could have with no problem). I also understand that the Jay Miners (sp) AmigaDOS and GUI is exceptional.

   Slightly less than using Workbench. Multitasking is limited to
   Desk Accessories/TSRs.

   It's an austere beast. Essentially, it is a minimal working set
   for a GUI based OS & UI. With TOS/GEM you can do most of what
   a Mac or Win user would want to do but on much less powerful
   hardware. It is somewhat Amigish in this respect.

Exactly...It kinda reminds me of some of those Sci-Fi scenarios when
Mankind is confronted with older, more advanced technology, and he is
in denial, or at the very least confusion... And even when Man's -
existing Technology is more advanced-they are awed by what was done
by the Elders before...

Well, there has been some debate, but I go with "The Operating System"...
I've heard "Tramiel Operating System" as well.

TOS is probably the single-most "friendliest" OS in existence...at least
as far as the OS's I've used, it is...Like the Amiga OS, its footprint
is very small, and uses resources very efficiently. There are apps that
you can "install' for almost every major form of picture/sound/anim so
that a double-click on the ext. (say *.GIF/*.JPG/*.TGA/*.MOD/*.WAV, etc)
starts the associated app and bingo!, the file is shown, played, run,
etc,.. File Ops are the most logical of any system I've used. Most of TOS
is in ROM so we don't have near the fear of viruses that the Mac/Win
world does...TOS runs well in an 8mhz enviroment...but of course, really
shines the faster you push it. There is lots more, but I just don't have
the room...Having owned Amiga's (A2000, A1200, and I still have a very
venerable old A1000 that I can't bear to part with because of Jay Miner
and his dogs signature) I can say (despite the ancient Amiga/Atari wars)
that users of both machines have more in common than with Mac/Wintel

hardware/software...I have an AMinet CD on my BBS as well as Atari and PC's...(umm...6 CD's total now) :) Oh well, I've typed long enough here I suppose-I hope I've at least shown you a small part of the TOS world, and if you are really interested, then by all means, download some of the various FAQ files about the ST/Lynx/Jaguar/Portfolio/Falcon/TT and the new clones...See ya 'round Cyberspace! :')

I hope that you know your GOD loves you, no matter what GOD you believe in.
Thank your GOD for life and ask your GOD to let you live as your GOD would want
you to. When we look closely at GOD we begin to realize that we all believe in the
same GOD, we may see GOD in different ways, but GOD will always be GOD. There
can only be one GOD, and that one GOD loves us all, and wants nothing but the
best for us. If your in doubt, just remember GOD works in mysterious ways, there
is
a reason for everything...

God thank you.

Someone

No, Linux. There is an experimental monolithic Linux release for the PCI
PowerMacs.

>>TOS = what's in ROM.
>
>MacOS= what's in ROM.

Nope.

MacOS was never shipped as an entirely ROM-based OS. Parts of it have
always loaded off disk. TOS is ROM-based (except in the early days, when
it was disk based solely because they hadn't cut it down to 192K to fit in
the ROMs as intended). Things like MultiTOS entirely bypass the TOS ROMs.

>>The simpler they are, the easier they are to port and improve upon.

That's really a mixture of unrealistic design goals and horrendous management problems (management problems are what sunk Atari, after all!).

>>>And HFS is blown away by MinixFS.

Correction. This is true for the traditional Finder copy routines, which are known to be way less than optimal. Speed Doubler, in addition to containing a faster 68K emulator, replaces the Finder copy routines with code that can copy at the maximum possible rate (i.e. as fast as the disk can transfer data in raw block tests). I have timed it; it achieves 5MB/s copies on my 5MB/s drive, and it hardly slows down even if you are copying a large number of small files.

Preemptive multitasking, not yet (except in a limited way), but MacOS has had true TCP/IP network support at the OS level for a very long time. Or is there some way in which MacTCP is somehow not "true" TCP/IP?

Open Transport is Apple's latest. Open Transport is basically a port of several UNIX related networking systems (STREAMS, the X/Open Transport Layer, etc.). It comes with drivers for TCP/IP and AppleTalk, and drivers are available for a whole slew of other network protocols.

>......And will never get either, since Apple has cancelled the development

Actually, the word is that OS 8 (Copland) is continuing development, but not necessarily in the same form that was originally discussed.

Yea you are a spoiled bastard.. The mailorder firms do have a 30 day MBG on
some apps.

So did you see any GateWays and Dells there? Probably not, but do well
anyways..

Wal-Mart and the thier superstores never did a superb job on the Mac. I
presume Apple has deamphasize the chain and concentrate on the ones who have
terrific Mac support. Their are many..Like ComputerTown and Computerware
chain..

Not when it includes the Apple 15' multiscan monitor.. The 6320 is no longer
manufactured and has been discontinued. Considering what he paid for it and
did include the monitor. So in essense it stomps on the Falcon for
price/performance.

The slowest desktop in Apple's retail arsenal is the $1500 6360. Not bad for
what you get compared to the Falcon..More computer/less money describes the
cheapest Performa in comparison to the Falcn.

Thats funny, I swore I had Mac TCP and Open Transport laying around in the HD.

Things TOS machines do not have are decent internet apps like a Netscape browser.

> ......And will never get either, since Apple has cancelled the development
> of CopeLand, the "next generation" MacOS that was suppossed to be pre-emtive.

Apple has cancelled Copland not Mac OS8..

I suppose selling millions of units annual is a sign of failure plus the addition of Mac OS clones..

As for Copland read above..

>

If you believe Mac World (Sinclap sure quotes them a lot.
are you taking over for him while he is on X-Mas vacation?).
you will never see a Mac O/S with the name Copland. They intend
to offer much small bug fixes and improvements rather than a totally
new O/S offering, again according to Mac World.
One thing is for sure. With Apple being so indecisive, clones
being produced that have the ability to run O/S's other than
the Mac O/S, and the Be O/S coming, the future will be interesting,
inculding TOS clones. One can only hope that for some strange reason
SGI drops the price on an INDY to $1999.95. We would then however,
have nothing to debate.

Mike

Hell, no! The day I take over for that moron is the day they put me in an institution. Mainly I'm here because I'm bored and I see a lot of people saying untrue things (many of them are overreactions to Sinclap, the Advocate Who Will Not Die).

I'll be going on christmas vacation very soon now myself, so if you see me drop out of this thread, don't be surprised.

>you will never see a Mac O/S with the name Copland. They intend
>to offer much small bug fixes and improvements rather than a totally

No. They intend to release "reference versions" every 6 months, and updates 3 months after each reference version. It is unclear what exactly will happen to the mass of code developed for Copland, execpt that the user interface and similar noncritical stuff will get added to 7.6 3 months after 7.6 ships in January. However, the general gist has been that OS 8 technology will be fully developed. They're just not holding up every piece of it to wait for the preemptive multitasking and memory protection parts.

The most plausible of the recent rumors surrounding Apple and Be had Apple using the BeOS application programming model on the microkernel developed for MacOS 8, with MacOS 8 APIs like QuickDraw GX, the device driver system, etc. If there is anything to these rumors, Apple is now more willing to abandon the legacy MacOS architecture in favor of a clean architecture with an emulator box for 7.x applications.

Indys are discontinued, I think. I doubt that SGI is going to drop prices that low soon. It's not their market.

Alphas, on the other hand, may be poised to jump on the Pentium Pro market. It's looking like the 21164PC, Digital's low-cost Alpha, is going to compete *very* well in price with the PPro, for certain markets.

Atari 1040ST 1meg ram, dual floppies, color monitor, mouse, joy stic, software atari 1st word, vip proffesional, starglider, flight sim, and other games, all original doc's and software, everything works fine, is in very good shape,
This is a nice machine, but just isn't being used, won't to sell, will ship COD + shipping, make an offer.

bmoore@carolinanet.com

```

I am, oce again looking at the computer market in an attempt to find a good home office system. With the increase in price of mainstream computers, buying something non-standard looks a bit more attractive. So I am looking for recommendations.

The system must run standard office productivity tools including a word processor, spreadsheet, database, drawing package and terminal based communications package. The word processor must support multiple proportional fonts in arbitrary sizes, multiple columns, colour output and inclusion of drawings. The spreadsheet must support at least 2000x2000 cells and ability to access and process all the functions from Lotus version 2 files.

The choice of system will be judged on ease of use, cost and reliability, provided the basic functionality has been met. The obvious system to compare with is the current low end Apple Macintosh Performa with a colour inkjet printer. This comes with Claris Works as standard which is a market leader in ease of use for an integrated office productivity package.

Any systems suggested must be complete and include any necessary software as well as all the hardware necessary, including a printer. Price estimates are important as well as information about sources for any software that is not bundled with the system.

I look forward to hearing any suggestions

```

Well, CAB is pretty decent, lynx also is, as are most other Unix VT
applications such as newsreaders, mail readers, IRC clients, etc..

Apple ships MkLinux with all the source code. Anyone who wants to write an operating system for the PowerMac can use it as a guide. Also, Be has sucessfully ported BeOS to the PowerMac PCI series and has indicated that Apple was very helpful in providing necessary hardware details.

newsgroups: comp.sys.atari.advocacy
x-mailer: Mozilla 3.01Gold (Macintosh; I; 68K)

After searching through a few hundred
doc's at the Apples developer site,
I found some information on a "bug"
with the Q840AV. Not to be specific,
there was a chip change in this model.
This chip had tighter timing requirements
than the previous Quadra line machines.
Some manufactures of expansion cards wondered
why cards that worked fine in Q700-900's
now would cause the machine to hang,
even with no bus activity.
With the timing narrowed, and the
aftermarket cards having a loose
timing tolerance, the cards failed.
There was a technical programming
explaination given to the developers
on how to bring their cards up to spec
with software solutions.
I only mention this because someone had
posted that this may not be a desireable
machine to run MagiC Mac with because
it had quality problems. The quality
problems, from the two or three hours
I spent reading, were with the aftermarket
hardware and not the Quadra 840AV itself.
If you need a PPC spend the bucks. If you
want to run MagiC Mac, enjoy running TOS
applications 4 to 6 times faster than a
Falcon and don't care about spending more
bucks for Mac software, get the Quadra 840AV.

Mike

Actually, I believe that they think that this will help them. Since PPCP boxes will probably ship in Q1 of next year anyone will be able to write an operating system for them. By providing PPCP operating system makers hardware details for the PowerMac line they might be attempting slow their obsolesence.

You can't compare Apple's retail presence to Atari's near zero retail presence. The mall software stores next to Wal-Mart that I have been to had decent section of Mac apps but at higher prices compared to MacZone. I don't know about you, I like to save money even it means calling an 800 number and paying $3 for over night shipping. Gotta make use of the bazillion Mac catalogs I recieve every month..

I keep all of the catalogs for the on campus demos to pass out.. I like to save my customers money..

I wouldn't go far as that.. In my lakes of the woods, I can count at least 5 retailers who have Macs..And this includes one Mac only reseller..Must of been the reason why the local Wal-Mart drop the Performas. Both were selling the same models at the same price. The difference was that the Mac reseller provided alot more support and the people have a clue..

If he wants to see Gateway... all he has to do is watch TV for

> awhile. They'll come to him, like any sane merchant.

And he/she wants an alternative Apple branded Mac can call PowerComputing. What is your point.

I wouldn't go far as saying that the Mac had half the space.. All I can say is that Iowa is saturated with Apple resellers..Must be blissed..Considering were sterotyped as being just rural..

You should get a car Jabba and get out more..

It doesn't have to compare. It really is quite irrelevant. Bashing
upon Atari will do nothing diminish that fact that Mac is diminishing.

$>The mall software stores next to Wal-Mart that I have been to had decent

Mall software stores? Really, you must be joking. Those places are
more likely to have more Atari (jaguar,lynx) software than Mac. Those
places stopped supporting Apple (mac & apple2) at around the same time
they gave up on the ST and the Amiga.

Only chain superstores carry anything Apple these days and you wont
find them at the mall. If you target audience never ventures outside
the mall the Mac is as dead to them as Atari or Amiga.

$>section of Mac apps but at higher prices compared to MacZone. I don't know

ROFL!  Only if it is was true.  PowerComputing is the fastest startup company
this year and will have sold hundreds of thousands of units this year.  Will
```

most likely exceed a million units for '97' Not bad for a two year firm. While Umax/Supermac will be a success as they are today. Plus Motorola has started cranking out units in the tens of thousands and will catch up to Apple's 4 million plus annual units in '98'..

Look for GateWay to enter the Mac market..

Thats interesting..I have yet to see anything Atari in these shops. Just wishful delusions by Jabba..

The local Software ETC has a nice size Mac selection. I still can't understand why they do well Mac app sales when you can buy mailorder and save a bundle.

Only chain superstores carry anything Apple these days and you wont

> find them at the mall. If you target audience never ventures outside
> the mall the Mac is as dead to them as Atari or Amiga.

Well what delusions.. Apple has over 4000 authorized resellers in the U.S. I count for five places in a five mile radius and just as many in the Des Moines area..

You need to get out some more..

> This is all fine and dandy if you actually go to the effort to reach

Huh? Apple does indeed advertise. I may not agree with their message, they do advertise. They advertised many times this semester in our student paper. I have seen their ads in other student papers. I have seen their ads in RollingStones, Fortune, Businessweek, Time, NewsWeek, and lots more..

You need to quit talking out of your ass.

>
> I bet a lot of corn farmers buy macs.

Typical stereotyping.. I have seen lots of Mac ads by resellers in the major papers such as the LA Times, Washington Post and the New York Times..

> They've got to know about the place first. They'll know about Gateway, they'll never know about Power Computing.

Yes they will. PowerComputing is the next Dell and GateWay. They have had excellent sales this year. They may most likely will exceed a billion in '97'. A critical mass to fund tv advertising.

Dell doesn't advertise as much as GateWay on tv.

>

What are you talking about? Apple sells million units annual and has sales of $10 billion annual.

Atari Revulutionaries coud not fill a sink hole. Thier arrogance widened it..

> I would. It does not discredit me to admit this as it does you.
>

You have been descridited..

> I do get out more. I'm easy driving distance from at least 9 cities with populations over 1 million. Yet in all of this mass of humanity, as opposed to cornstalks, I can find no great Mac presence. Where is it hiding?

Open your eyes..

>TOS is no more than a hack put together by the now defunct Digital Research..

Actually, it's GEM you moron. TOS is GEM + GEMDOS for the ST.

Well, this hack provided a filesystem, virtual devices, virtual device api's, a windowing system, a windowing manager, a desktop shell & a primitive scheduler all in 200K and did it in such a fashion as to be trivial to port and easy to augment.

This trumps MacOS by quite a bit.

>
>TOS has no were the functionality, features and technology that is tied to the
>Mac OS.

The IDEA is tied to Xerox PARC, actually. It is an idea, not actual technology that X, Digital Research or MicroSlop 'may' have swiped.

However, Apple's intent to assimilate BeOS is actual copying of technology.

Despite Apple somehow being capable of generating their own unique intellectual property or despite MacOS being somehow superior (to anything), Apple must depend upon someone else's technology and not just ideas or concepts in order to keep up with an orphan platform. Apple must do this despite all of it's admittedly superior resources.

It is truely sad when the OS offerings from an orphan can compete with a giant like MicroSlop and the OS offerings from another giant cannot.

Your blind loyalty is a greater threat to Apple than MicroSloth and all the PC vendors combined. You nullify what proper market forces might be in place to coerce Apple to do what is required to compete in a larger market. Now they have lost whatever advantage they may have had to mitigate their higher prices and less support.

Apple has gotten a free ride from the likes of you in the past and is now paying dearly for it.

Macs have no retail presence at this time. Without this, people will begin to consider them dead. There is nothing in the public eye to give people a good impression of Apple with the most recent visible coverage being about Apple's imminent demise.

A few lines in more financially oriented publications will not counter this. Then the general public will see the Mac's pathetic storefront presence and jump to conclusions.

Mail order chain backorders wont help. Furthermore, those numbers are rather meagre when compared to the rest of the market. This is the market that Apple actually competes against and gets compared to. That you can best a 10 year old orphan [in PR] is of no consequence.

The percentage of consumers that exist within that market really is minscule. THAT is not the public eye. A price tag at a college store (that is assuming that there is shelf space at the college store) where no one may venture to is not even the college public eye let alone so in general.

>

All I need do is look around. Aptiva is visible as is Gateway 2000 without ANY effort to find them. Clones still haven't shown their faces any where near the general public. I have yet to even encounter print ads for them in publications one might expect a non-MacWorshiper to read. Further that with the general lack of retail presence and you have a grim picture.

It may not reflect reality but, it need not do so. That is the point you cannot seem to grasp. An elitist attitude and the unwillingess to proper PR wont get Apple anywhere.

The best you can come up with is educational pricing.

You're running only one program at a time. When you quit it, all its memory is freed up, as you say. However, if you have a multitasking operating system, it is possible to get a program stuck in the middle of memory. Run program A, run program B, quit program A, and you will have fragmentation because B is still sitting in the middle of memory.

Ataris would have massive problems with this issue, except that most of them don't run a multitasking OS. The model on Atari tends to be that you run a single application program at a time, which takes up all available RAM. Desk accessories are there, but they load during the boot and cannot be quit, so they don't cause fragmentation.

VM completely bypasses this problem by virtualizing addresses. This means that Program A might think it has an address space starting at address 0 and going to address X, but it is actually stored in a relatively random jumble of physical addresses, which are not even necessarily in increasing order. Memory is allocated in chunks, typically 4KB, referred to as pages. The lower bits of a virtual address are the offset from the beginning of a page, and the upper bits are the virtual page number. The CPU automatically translates the virtual page number to a physical page number, typically using a Translation Lookaside Buffer (TLB). (A TLB is a cache which caches the systemwide page table, which is typically a megabyte or two of RAM set aside to store all the virtual->physical mappings.)

An operating system can change the virtual->physical page mappings so that pages can be moved wherever it wants in physical memory. And even if memory is horribly fragmented, the OS just chooses whichever pages are free to allocate to a program; as far as the program is concerned it has a linear and unbroken chunk of memory. Pages can be swapped out to disk, too: just set a bit in a page table entry which says it is not resident in RAM, and the OS will be called when an access to that page is attempted. The OS can then read the page back from the disk and restart the program which needed that page.

I'm not saying they were unreliable. I'm saying that, for myself at
least, the 1040STe keyboard felt like it had mush behind the keys instead
of springs. Personally, I like IBM (True Blue, not cloner) full click
keyboards, and almost everybody I've ever talked to doesn't really like to
type on a keyboard with no feel whatsoever. At least not if they are
touch-typists. (Hunt&peck typists seem to get on fine regardless, because
if you have to look at the keyboard you don't need the physical feedback
from the keys as much.)

Indeed? It's trivial to port and easy to augment because it implements very, very few services compared to the MacOS. GEMDOS is essentially a slightly cleaned up DOS (if you look at the calls, they're nearly identical). GEM is a very simplistic windowing system. It all fit in 200K because it did so little.

Actually, as far as size goes, System 1.0 for the Mac was probably more impressive. The Toolbox routines sat in 64K of ROM and the rest of the OS had to share 128K with application programs. And it had more features than TOS.

(That's not really surprising, considering that Apple had been working on the Macintosh System for several years, starting from a blank slate, while GEM/GEMDOS was essentially a bolt&go OS put together in very little time.)

Macs have never had much of a retail presence. Traditionally, mail-order is where the bulk of Macintosh sales (hardware and software) take place.

That's not to say that the current problem with retail stores dropping Macs doesn't disturb me. But it's not the kiss of death you make it out to be.

Well, everyone, I am typing this from the keyboard of my new Performa

PowerMac 6320, which I bought on close-out from Staples. As an Atari user, I have a number of observations about both platforms that I hope will quell much of the BS on the net:

Where Mac excels beyond TOS machines:

1) Multimedia (at least in this machine). I was able to record, edit, and playback video without a crash, or peep.

2) Application availablity. 'Nuff said.

3) General speed (surprise - a 120 MHz 603e is faster than a 16 MHz '030 (though it doesn't feel that way sometimes!).

Where TOS excels beyond Mac machines:

1) Stability. I have crashed this Mac more that five times as frequently as my Falcon030.

2) Multitasking. Even using DA's for multitasking, Falcon destroys MacOS. I attempted to run a simple Kermit transfer in the background from ClarisWorks while running the word processor from within Claris-Works. Heh, stopped that quick - characters were dropped and took several seconds to appear on the screen. On the Falcon, STalker and AtariWorks multitasked seamlessly in 4 megs under MultiTOS, without any delays at all!

Folks, choose your machine. And use it and enjoy it.

BR Miller
Boston, MA

: because of Iron Soldier on the Jaguar and Music Composer on the Atari
: 8-bit. Microsoft asks "Where do you want to go today?" Maybe I should
: say, "Where you yesterday and would you like to go back today."

I can't say That I ever lost my facination with my first ever computer, a 1040stfm. Having worked with PC's and seen a little of the apple and commodore offerings of the day i decided that the one meg st was the the pick of the bunch for my budget. I liked the midi interface, the commercial and free/shareware software and the games..
I didn't like the mouse or the position of it's port but these irritation were easily fixed. I hoped for a long working life and to accumulate enough software before commercial support dried up (as it always does for any given platform).

So now you know where I was yesterday and you know what,, I'm still there. I'ts not so bad either. Second hand atari gear has to be fantastic value
I recently bought a one meg stfm, a one meg ste, a mono monitor, a colour monitor, and a 30 meg hard disk and still had change from $400.
As for software.. just hang about here (on the internet) and you won't have too many problems. I personally am waiting for the www package with ppp.
I can't use slip because my isp can't get it to work on his linux system!

I snipped your comment saying that atari was dead. True for the corporation but the movement lives on especially in germany of all places.

It just like with cache...more is not necessarily better. I'll take TOS's clean, hard 'n fast OS (especially the file ops) over any other OS on the market anytime...everytime...! :)

AFAIK, (from newsgroup browsing-since I don't actually use them myself) both Geneva and Magic handle these problems well...

FOR SALE: ATARI 1040 ST - SYSTEM AND SOFTWARE !!!
                   ATARI 800 - SYSTEM AND SOFTWARE !!! (Listed Below)

****
                ATARI 1040 ST - SYSTEM AND SOFTWARE !!!
****

***** Best Offer ****** For Everything *****
        (plus shipping costs)
Will sell components separately.

HARDWARE: Original boxes and documentation.

ATARI 1040 ST and ATARI SC-1224 COLOR MONITOR
ATARI SH-204 HARD DRIVE
ATARI SX-212 MODEM - 2400 Baud

SUPER CHARGER - TALON TECHNOLOGY (converts Atari to IBM format)
SF354 3-1/2" EXTERNAL FLOPPY DISK DRIVE
MASTER-5S 5-1/4" EXTERNAL FLOPPY DISK DRIVE
WIRELESS REMOTE CONTROL JOYSTICKS - (2 on 1 base)
(1) QUICKSHOT JOYSTICK (2) ATARI JOYSTICKS
* All hardware purchased in 1990. (except for 2 original style joysticks)
* Original cost new in 1990 was $2,000+-

ATARI ST SOFTWARE: All original disks.
(All software believed to be in working order, but not guaranteed)

BOOT DISK | ST LANGUAGE DISK
LANGUAGE DISK | 1st - WORD
PROCOPY | COPY II ST - Disk backup utility
PC/InterComm
SUPERCHARGER (images) | ST Informer disks - 1291,192,392,492,592
REGIONAL COOKING COLLECTION AMERICAN COOKS CHINESE
ADDITIONAL PROGRAMS LOADED ON HARD DRIVE, HOWEVER NOT CATALOGED.

GAMES: (All in original boxes with instructions & 1 disk,
unless otherwise noted)

ARKNOID (instructions, no box)
DUNGEON MASTER (instructions, no box) - (also comes with print outs of maps and story)
MISSILE COMMAND (instructions, no box)
OBLITERATOR (instructions, no box) (2 disks)
SUPER CYCLE (instructions, no box)
TIME AND MAGIK (instructions, no box)
The WRATH OF NIKADEMUS (instructions, no box) (2 disks)
WARLOCK (instructions, no box)
PRINCES IN AMBER (box, no instructions)
TIME BANDIT (box, no instructions)
XEVIOUS (no box, no instructions)
TEMPLE OF APSHAI TRILOGY (no box, no instructions)
ADVANCED DUNGEON & DRAGONS - HEROES OF THE LANCE (no box, no instructions) (3 disks)
ADVANCED DUNGEONS & DRAGONS - HILLSFAR (2 disks)
BARBARIAN S.D.I | The BLACK CALDRON (2 disks)
BLOOD MONEY | CHRONO QUEST (4 disks)
CRYSTAL CASTLES | DEATH BRINGER (3 disks)
DRAGON LORD | FOUNDATIONS WASTE (2 disks)
GATEWAY (2 disks) | GAUNTLET (2 disks)
GHOSTBUSTERS 2 | The GUILD OF THIEVES
IRON LORD (3 disks) | JINXTER
KNIGHT ORC (2 disks) | The KRISTAL
OOZE (2 disks) | OUT RUN
QUESTRON II (2 disks) | NINE RINGS OF ZILFIN (3 disks)
ROAD RAIDER (2 disks) | ROBO COP

ROGUE | SPACE HARRIER   (2 disks)
WANDERER ROAD | WILLOW   (2 disks)

You'd really take TOS over any other operating system on the market? Does
this include IRIX and BeOS?

Actually, Apple's Performa line of Mac's are bundled with monitors,
keyboards, modems, etc. The only exception to this I believe is the 6400.

Actually, you can pick up a brand new Performa 6400 for about
$2000.00US. This is one very usable and capable machine.

Michael Grove <mgrove@ridgecrest.ca.us> writes:
>Wrong! It clearly states in the MagiC Manual, in English,
>that VM must be disabled. This has been true for both versions
>that Toad has had imported to date.

As I said, if you cared to read it instead of just rudely shouting
"wrong", older versions worked with VM. If Toad (whoever they are)
have only imported two versions, then they clearly haven't imported
them all.

VM support was changed when the PPC-compatible version was produced.

Sorry, Wrong again! For the sake of not having to look-up every
revision that Toad has imported (from the same place you buy your
copy) I stated two revs. In fact it has been 4 or 5, I have forgotten
the actual number. In anycase, the first release of MCM, in the U.S,
from System Solutions, imported by Toad Computers, inside the manual
it states to disable VM on the Mac as it does not work (both with MCM
and the Mac O/S:). This is the version prior to PPC support. So if this
version is prior to PPC support, and your stating that it wasn't changed

until the PPC was available, then your statement is false. If I could
have possibly misunderstood what you stated, please try again.

Mike

Well I'm not going to abandon it, I'm going to keep my ST still for a
while and just gradually move across, and its going to take a loooong
time before something can replcae Tempus. And there is no way that
I'mm move to a Wintel machine by choice.

>So much more software and
>hardware for soooooo much less money.

I'm not bothered about the quantity but the prices of software are well
out of line.

A little to good I'm afraid, if you only want to draw a few pictures
you don't buy SGI.

This Powercomputing clone lark is not as true as it appears,
apparently the main Apple clone maker is owned by Apple and Olivetti.

I won't post his name but he has a studio in Brooklyn, has worked with many
top artist in the music field (several gold records). His studio was profiled
in an issue of "EQ" a US magazine. His secret is a C-Lab Falcon with CAF.
He also owns a PowerMac 7600, not to mention a few other pieces of gear.

To be honest its not the gear, its how you use it or do you know how to use
it. Many gold records are still recorded on paper. The Falcon or any other
platform with a sequencer (or better a combined audio/sequncer) is a handy
tool in the song writting (composing) process. At least for me. Still, all
my recordings end up on a ADAT tape.

Non-linear for jumping around will working on parts and when everything is
(oopps "will" is supposed to be "while") done, it all goes onto a ADAT.
A Falcon with the latest version of CAF or AudioTracker very stable. I have
multi-channel analog ins/outs, S/PDIF in/out and a ADAT Light Pipe in/out.

Regards,

Rich

Yes.

>It's trivial to port and easy to augment because it implements
>very, very few services compared to the MacOS.

It implements functionality for dropdown and popup menus, windows, alert
and dialog boxes, provides 1000 RGB levels (24 bit graphics cards only
need 256), several device independant routines for drawing circles, arcs,
rectangles, lines, etc., font management (today also including Speedo (tm)
and TrueType (tm) fonts), a far more acceptable memory management than
MacOS, etc.. MultiTOS (or N.AES) provide loadable file systems, preemptive
multitasking and many more very unix-ish functions.

>GEMDOS is essentially a
>slightly cleaned up DOS (if you look at the calls, they're nearly
>identical).

GEMDOS is the weakest part of an Atari's OS, but it's not a part of GEM.

>GEM is a very simplistic windowing system. It all fit in
>200K because it did so little.

See above, define "little". MacOS didn't even come with subdirectories
("folders") when it was new.

>> If you never go native, then the 840 is a good bet. But when you realise what Mac s/w is out there...

I don't see how you can't go native today. More and more apps today are native only or barely runs decently on the 68k Macs..

> And you will wish you never got started:) After adding a Mac to my collection, I have been disapointed more times than not with the quality and pricing of the available software and hardware. You will really hate the Mac O/S after moving from the Atari platform (especially if your using a Falcon). The file system really sucks. Try editing in a directory containing a couple thousand files, or renaming multiple file names. Can't be easily done. Kobold handles this without problem. Go to Walmart and try to purchase some Mac software on a Friday night binge. Good luck.

Quality and pricing of apps compared to TOS ones is not good? Please list the apps and prices compared to the equivelant TOS ones..

Why not try the Mall stores and the superstores.. Or try the mailorders like MacZone, MacWareHouse, MacConnection, ClubMac, GDW and MacMall? I rarely buy from the mall stores.. Why should I pay at least $30 more per app when I can get from one of those mailorder firms the next day for additional $3 and no tax? I am sure you recieve those nice glossy catalogs weekly..

> Anyway I don't think he was asking for advice on which Mac to purchase for the purpose to "migrate" over to PPC apps, he ask which Mac would run MagiC Mac the best. By far the most cost effective method is the Quadra 840AV. With a cheap clock speeder, you might get up to 46mhz, easily keeping up with the PPC's running MagiC Mac. You get the Mac onboard video. Which PPC includes that for under a grand? The cheapest Mac clone will run you $2200.00 for included video (DC20).

You're money.. The Q840AV had some quality issues that may have not been resolved after discontinuation.

I don't know what world you live in, The cheapest Mac clone now is the Umax

C500 at $1299 for a 160mhz 603e, 16 megs ram, 1.2gig, 8xCD, 16 bit sound, keyboard, mouse and software bundle.

Infinity is selling clone kits starting at $899 for a barebones Tower unit that includes a Motorola motherboard(603e - 160 mhz). Prices will drop as usual..

Where selling the Performa 6400/180 for under $1500..

I don't see the performance gain for an 040 Hades when the price is higher than
the Umax 600-240Mhz 603e Tower for $2299.. The C600 just smokes it..

Actually the mac clones and some Apple models are cheaper than equivelant
Pentium clones. Plus you spend time actually using the machine instead of
figuring out the ins of wintel..

Oh, please..I don't think you can articulate ideas like he can.. If you could, who needs Rush?

I know a lot of Conservatives who despise Rush. They know how to think for themselves and articulate ideas and thoughts. And these conservatives despise your wanna be's because you need Rush to think for you..

We do not have a popular Liberal one because Liberals do not need one to think for them..

There is one thing Rush needs to work on for the dittoheads.. Learn to write and articualte a thought on your own..

What's a Commie? Sounds like McCarthyism here..

I hate to tell ya, we do live in a socialist country. We hand out over $200 billion in corporate welfare..

Macs have no retail presense? Have you told this to Ireland Technologies down the street from where I live, Best Buy, CompUSA, OfficeMax, ComputerWare, ComputerTown and to much to list..

I don't know what you smoke on your homeworld, Can I have some...:)

> A few lines in more financially oriented publications will not counter
> this. Then the general public will see the Mac's pathetic storefront
> presence and jump to conclusions.

So RollingStones and other lifestyle Gen X publications does not count?

> market that Apple actually competes against and gets compared to. That
> you can best a 10 year old orphan [in PR] is of no consequence.

Ha ha ha..So desparate..Mailorder is meager compared to the rest? Have you told this to GateWay and Dell?

Apple is holding their own and letting the Mac clone firms to expand the market..

> The percentage of consumers that exist within that market really is
> minscule. THAT is not the public eye. A price tag at a college store

> have a grim picture.

GateWay 2000 is mailorder only. No retail presence except for the Destination line which has not done well.

You need to lookelse were from the star trek rags. I don't see this general lack of retail presense. At least not in Iowa..

>
>   It may not reflect reality but, it need not do so. That is the point

Actually it is the original Mac OS 1.0 that ran on a 128k Mac.. Such efficient
and tight code.  Progress tookover and the added hardware became commodity.

>    This trumps MacOS by quite a bit.

I don't think so..

>>TOS has no were the functionality, features and technology that is tied to the

Apple is acquiring the technology with hard cold cash..  There is a difference
bewtween legal means and pirating/copying..

```

> Apple must do this despite all of it's admittedly superior resources.

Didn't Atari try to copy apple speak to keep up.? Like adding a laser printer and publishing app. Not very original..

> It is truely sad when the OS offerings from an orphan can compete
> with a giant like MicroSlop and the OS offerings from another giant
> cannot.

I didn't know the Mac is an orphan.. One is sold every nine seconds..

> Your blind loyalty is a greater threat to Apple than MicroSloth and all

Please explain further.. Also quote the higher prices to..

> Apple has gotten a free ride from the likes of you in the past and is
> now paying dearly for it.

And how is that? I have benefited from their screwups..Like buying a box with a gig and awesome software bundle new for $899.. Much cheaper and useful to boot than a Hades..

```

Have not used those two...so I can't honestly say about them. (but oh, boy
do I doubt it!)

The only other OS that I've used (and that includes TOS, DOS, Win 3.x,
Win '95, Mac Sys. 7.x, and Linux) that I would even remotely consider
over TOS would be WorkBench 3.x on the Amiga... :)

I agree, application availability is better - but many of the applications I am running on my PowerMac are not of substantially-higher quality than my better TOS ones - Papyrus, for instance. Certainly, there's no need to "upgrade" if you are only looking to get a better word processor or DTP program, since the TOS ones are quite comparable to the Mac ones (and TOS is more stable).

I grabbed my Performa 6320 (120 MHz 603e) for $1500 at Staples, including monitor, KB (oooh, they even gave me a keyboard! :')), mouse (whoohoo! a mouse! how generous! ;'>) and a load of CDs with a lot of crappy software and some decent stuff.

I am running SoftWindoze 95, which is competent, and a tad faster here than on some friends' 486/66 DX2s. I plan to get MagicMac, so I can continue running some of the better TOS apps (like Calamus SL). Purchasing a replacement for Calamus on the Mac platform would set me back over $700, something I'm not too keen on right now.

Really, it's not as bad as JEDI infers, nor as blissful as PSD proclaims.

PETER SINCLAIR-DAY (sinclap2954@cobra.uni.edu) wrote:
: TOS is no more than a hack put together by the now defunct Digital Research

GEM means "Graphics Environment Manager" and was essential written by Gary Kildall and team at Digital Research. GEM embodied the best of the office analogy graphical user interfaces. Elegant, coherent and logical. Gary Kildall is not with us anymore (so he can't defend himself from you) and GEM is now owned by others. TOS was written by a team at Atari and, for the time, one of the best of the operating systems. GEM and TOS work very together.

I really thought you were interested in recruiting Atarians to the Mac. I think you are really an Atarian who is angry that the Tramiels didn't develop your favorite computer to full potential.

Why don't you spend your time over at the Mac groups helping newcomers learn their machines. Wouldn't that be more gratifying?

I use IRIX extensively and I beleive that it is the best operating system
that I have ever encountered. It provides all the functionality of UNIX
with an absolutely beautiful and functional X/Motif interface.

I've looked at the features offered by QuickDraw and GEM. QuickDraw wins, hands down. It is easier to use, more flexible, and offers a more complete set of graphics primitive calls. It has very powerful features, like clipping regions (which, as far as I know, exist in no other graphics API). Some of the really simple things, like the ability to create offscreen buffers that can be drawn to with the standard calls, are completely impossible in GEM (unless my memory deceives me).

(BTW, just in case you were wondering, QD provides 65536 levels for each primary color -- its internal color representation is 48-bit.)

> a far more acceptable memory management than
>MacOS, etc..

Are you kidding? Basic TOS has *no* memory management, or at least not enough to talk about. It just runs a program and gives it all the free RAM in the machine. (We were talking about what fits in 200K, remember?)

> MultiTOS (or N.AES) provide loadable file systems, preemptive
>multitasking and many more very unix-ish functions.

MultiTOS was crap. I say that from experience. :)

I've never used N.AES, whatever that is.

In any case, these are *extensions* of TOS. The original message said something to the effect that TOS was better than MacOS because it was trivial to port and easy to augment. I was pointing out that these things were due to the extremely spartan nature of TOS.

>>GEM is a very simplistic windowing system. It all fit in

>("folders") when it was new.

Yeah, and it was new in 1984. I'm pretty sure HFS got introduced by the time the Atari came out. (I think it's obviously no argument that HFS blows away the FAT file system used by TOS.)

If there is more than one logical address space, that means that addresses are virtualized, which is what you need to avoid fragmentation. VM, virtualized adddresses, and memory protection are so interrelated that it is unlikely OS/2 can really stop having a virtual addressing system. (Nor would they want to, since good memory management is a lot harder when blocks have to be physically contiguous.)

>Can someone explain one aspect of the PowerMac VM to me please?
>A Get Info on an application typically says something like "minimum
>memory requirement reduced by 1300K if running with VM on".

When VM is on, the PowerMac treats the executable code of a PowerPC native program a bit differently. The executable is not allocated inside of the normal address space. This is because the program file itself is used as the backing store, instead of the systemwide swapfile. That's possible because PowerPC code, by definition, is never modified once loaded from a file. Since all PowerPC program code sits outside of the main address space, it effectively isn't taking up any of that address space. That's what allows the reduction in minimum memory requirement.

The number in the Get Info box reflects the exact size of the program's code fragment. If the file is actually larger, that's because Macs store a lot of stuff besides code in a program file.

You can improve this. Apple tends to put a ton o' crap in the Extensions folder that the typical user doesn't really need. One big thing is that if you aren't on a network and don't use an AppleTalk printer, you can turn off AppleTalk to regain some memory and speed.

I highly recommend Speed Doubler; if you can afford the 800K RAM penalty it makes the machine a LOT snappier. Sorta like TOS+Warp 9. :)

>Where TOS excels beyond Mac machines:
>
>1) Stability. I have crashed this Mac more that five times as frequently as my Falcon030.

You might want to get your System upgraded to 7.5.5, if it isn't already at that version. 7.5.2 and 7.5.3 have had notable stability problems. 7.5.5 isn't perfect, but it does seem to be a lot better.

>2) Multitasking. Even using DA's for multitasking, Falcon destroys MacOS. I attempted to run a simple Kermit transfer in the background from ClarisWorks while running the word processor from within Claris-Works. Heh, stopped that quick - characters were dropped and took several seconds to appear on the screen. On the Falcon, STalker and AtariWorks multitasked seamlessly in 4 megs under MultiTOS, without any delays at all!

That sounds like a Claris Works problem. I am able to crank up multiple FTP sessions in the background on my Mac with no problem. The communications tools in most "Works" programs are notorious for being less than solid.

Could someone please tell me what this disucssion has to do with video games?

Other than the fact that -- depending upon your political perspective -- some would want to see a game where you save Rush from the liberals or destroy Rush as a liberal.

Please take stuff like this to email or the approiopriate group.

And for the record, I have voted for both Bush and Clinton.

m ike dougherty

Offscreen bitmaps are IIRC implemented in NVDI >= 3.0. Clipping areas,
though, are not.

MultiTOS was never finished (the AES was still not completely adapted to
run sufficiently fast under MiNT), that's why. Version 1.08beta was much
faster, according to it's testers. And even MultiTOS needs much less
processing power than MacOS.

>I've never used N.AES, whatever that is

A replacement for the MultiTOS AES.

>In any case, these are *extensions* of TOS.

An AES is no extension, it's an elementary part of GEM.

>The original message said
>something to the effect that TOS was better than MacOS because it was

>were due to the extremely spartan nature of TOS.

Nope, they are due to the portability and easy improveability. Products
like MagiC show how easily clean GEM and TOS programs run under a preemptively multitasking environment, MultiTOS or it's inofficial heir N.AES
show what "easy augment" means, just like NVDI, MinixFS or MiNTnet do.

And HFS is blown away by MinixFS.

Thorsten

choose TOS!!! :)

AND what the *heck* is your problem with editing???????? You've really
got to go back and read the instructions!!!!!!! Just look at that mess
below...I bet your Mama never taught you that! She would probably be
soooooo ashamed! :)

(apologies to all for not editing the mess below)

NVDI and NAES are not 'extensions'. They are REPLACEMENTS.
GEM is structured in a well organized and layered fashion.
Each level can be replaced quite independently of the others
so long as the base API spec is adhered to.

>
>>>GEM is a very simplistic windowing system. It all fit in

It was made to fit the machine. It's a shame no one ever bothers
to do that anymore. GEM austerity surely trumps planned obsolecence
and OSes that cant fit into the memory space of the machines that
they were delivered with.

Hey!

This is a thead relating to video games, not stupid poltical liberals and conservatives crap that SinClap made the whole thing out to be.

It's bad enough having him come on the Atari ST newsgroups saying how crap the platform is, now he's pushing liberalism in everyone's face. You think he's a big Hollywood producer or something.

Everything has it's place...

ST's, not Mac's

and video games, not politics

Have the right to speak your mind, but use some bloody common sense and responsibility!

BTW, before anyone balls about me crossposting...1) It's already crossposted before I even responded to it and 2) I'm trying to stop it from getting out of hand.

As for Jag controls, I really was hoping they become as wide spread as the Sega controlers. I really would like to have all ST computers to use those. So if alot of people do buy them, then let me know...then I'll feel better :)

Using a soapbox as a footstool instead...

When the conventional media harks upon the imminent demise of Apple, their lack of presence in the marketplace only reinforces this idea to those who might otherwise consider a Mac.

The desperate advocacy attempts that too closely resemble the Atari Revolution don't help either...

> Mall software stores? Really, you must be joking. Those places are more likely to have more Atari (jaguar,lynx) software than Mac. Those places stopped supporting Apple (mac & apple2) at around the same time they gave up on the ST and the Amiga.
>
> Only chain superstores carry anything Apple these days and you wont find them at the mall. If you target audience never ventures outside the mall the Mac is as dead to them as Atari or Amiga.

BZZZZT! Wrong. I have found dozens of titles for Macintosh in "superstores" all over the country. Does it have the same quantity as PCs? No. But it has beeter quality. Does quality of applications exceed the Falcon? In some areas, yes. In other areas, no. Internet software, particularly CyberDog, and authoring tools - are more mature, albeit more expensive than, Falcon systems.

If you're looking for greater software, hardware, and retail availability, Mac does just fine. Of course, you have to be lucky like me and grab one on closeout so you can afford the Apple-badged ones. There is a firm called APS that sells Mac clones @ 120 MHz for $1399, if you're looking for an el-cheapo system.

But why are we arguing about this? Within two years, we shall be able to run TOS and BeOS and MacOS on the same machine under a Power PC processor, and we can run the best of all worlds.

And retail software support is becoming marginal at best - look at the Babbage's bankruptcy for an example. The Netscape model of selling software via the web will take off as never before. Believe me as an Internet marketing consultant.

Have I abandoned TOS? Hell, no! Much of what Petey says about TOS is untrue, and TOS is still very fast and flexible. But I need more updated tools in Internet authoring. I need a system that has more software availability. That's why I bought a Mac.

I have my original ATARI Mega 4 ST and an accumulation of peripheral stuff - modems, printers, scanners. I still use all this stuff regularly. Never did abandon it, actually. I have a PC - p75 running WIN95 and a bunch of other stuff, but it seems all I really use this beater for is the Internet. I would dump it all in a minute if there were something comparable to NETSCAPE that I could run on the ATARI. I never did think much of the PC and having acquired one and learned to program in VB and VC, if find that it is still just as easy to write a bit more code by hand in MWC or GFA. All the bells and whistles are BS!

A finished program in VB - with all the support modules - is around 2.5 meg (example) while the same program with the same look and feel in the custom interface and done in GFA 3.5 is only 300k! and 200k of that is the custom interface!

ATARI rules!

I recently tried the MagiCMac demo on my PowerWave 604/132. Keeping in mind that this =is= a demo and may not perfectly reflect the full package, and keeping in mind that the three anims I multitasked were very low end, the overall feeling I got was that this thing ran 6 times as fast as MacOS. What I'm wondering here is whether this really reflects the kind of speed I'd get from the package, and whether the available apps will reflect this speed as well.

Please consider that I have no previous experience with Atari computers. I'm not here to bash anyone. All I can say is that I found the speed and PMT breathtaking, and I want more! :>

Best;
Steve

>wishful delusions by Jabba..

No, the delusion is all yours. Such places will likely be about half
dedicated to console games and half dedicated to PC software. A few
will still have Atari closeouts. This really says nothing of the Atari
console market. It's just that those platforms were given somewhat of
a chance. These remants are left over from that.

Even that meagre presence is quite a bit more than NOTHING, which is
what they have in the way of apple support.

>

>area..

Well, that explains it. All the apple Dealers are sitting about
in Iowa cornfields, incompetently trying to mock Gateway, while
real population centers are left desolate.

Oh, I forgot... CompuUSA and BestBuy probably count as resellers...

This would be much like McDonald's having all of their many locations
tucked away in some deep dark corner of a Taco Hell.

Oooohyeah... all those students with all of that negative cashflow...
...and who have easy access to more computing resources than they
even need...

>RollingStones, Fortune, Businessweek, Time, NewsWeek, and lots more..
>
>You need to quit talking out of your ass.

I'm not. However, print advertisements for PC products quite
dwarf Mac ones. In fact, in that domain, the situation probably
appears WORSE.

Nevermind that not ONE of the cloners was mentioned ONCE.

It would appear, that you only bolstered my point.

In print, Mac is drowning in a sea of clones while Mac's own
cloners are nowhere to be found and not counteracting any of the
PC-tide.

So Mac prices and less support keep the masses away, while the
'converted' jump ship to the cloners.

In the end, the only visible 'Mac' diminishes even more in real terms.

>papers such as the LA Times, Washington Post and the New York Times..

You mean resellers like... CompUSA and... BestBuy?

With friends like that who needs enemies...

Besides, such 'ads' don't generally give any preference to Macs.
They just show how expensive the Macs are...
...how genuinely lame...

It's not stereotyping, BTW. I've driven through that part of the
country. It's downright desolate compared to the rest of the
country. It makes Indiana look like the big Apple.

>

       MagiC, in it's original form, is designed to be able to do what
```

it does with hardware comparable to a Mac Plus (Atari ST).

Take that level of efficiency, and then apply the power of a more contemporary machine to it, and the effect you've produced should not be at all unexpected.

Available apps will be limited however. Atari is an orphan. However, unless you have some pressing professional need, this should not be too much of a problem.

>
> Thats funny, I swore I had Mac TCP and Open Transport laying around in the HD.

Hallooooooo, don't you get _anything_, I said at OS-level!

It easy to have a pheudo-network socket running as an application, that method is also being used for singleTOS-users which is also co-operative.
It utterly impossible to have sockets in MacOS, due to it's outdated architecture being co-operative just like plain TOS.

The only things that is "updated" in MacOS is the user-interface, but it's like an old shined-up car, real nice to look at, but doesn't do shit for engine performance.

> Things TOS machines do not have are decent internet apps like a Netscape
> browser.

It's funny you always keep talking about NetScape, is that all you Mac-owners
really do when your networking ?

And by the way CAB is getting better and better by the week. In fact the only
thing it still doesn't have is the JAVA-virtual machine. Frames, animated GIF's,
netscape-extensions, real-audio etc.etc. are all part of the CAB-support.

> > ......And will never get either, since Apple has cancelled the development
> > of CopeLand, the "next generation" MacOS that was suppossed to be pre-emtive.

> Apple has cancelled Copland not Mac OS8..

And ? Will MAC OS8 be pre-emtive and have BSD-socket support like so many
other decent OS'es like WindowsNT, MiNT, LiNUX, SOLARIS, IRIX, AMIGA-OS,
FreeBSD etc. ?

If so, congratulations!

- If not, and it's just another "souped up" user-interface, than no-thanx...

It really seems that you're always thinking of the U.S., when it comes to the Mac
market. Have you ever considered that there are a another world outside where
the conditions are quite different ? Like Europe for instance.

By all means the Mac plays a little part here in Europe, but it definitly
has it's difficulties in keeping on the current market. The only real market
it has are specialized - the consumer market and student market is 99.5 %
PC-relative. And there's a good reason for that. Esspecially for a
computer-science student like myself, I would not be really fond of working
with a Mac, the MacOS simply doesn't have the power I need. I'm not
talking CPU-speeds or graphics, but OS-features in general. I have worked
with Mac's, have one myself, they are good computers for some things, but
they're definitly not _the ultimate solution_. My Falcon fills many of
my needs better, than the Mac.

> As for Copland read above..
>

You are out of line. Firstly, I am not a "Mac advocate," but am a TOS user who recently bought a PowerMac. Secondly, your attack upon my literacy coupled with a subtle change in literary devices suggests a mendaciousness which I find scurrilous. :') You have a real hate of Macintoshes, and are the Peter Sinclair-Day of the Atari userbase. You intimated that Macintosh software and hardware is difficult to find, and that, in general, Mac users have to REALLY SEARCH to find support. It simply isn't true, at least not in Boston, Massachusetts, USA (which may be different in many ways from the rest of the country, but I doubt in computer support, it is all that different from other cities).

JEDI wrote:

120 MHz is "weak" by today's standards? Why, foolish me, I thought that those $2,000 Sony and IBM systems all ran at 120 or 166 MHz. . . I looked at the $1,000 Packard-Bell Pentiums. What quality construction. The mouse ergonomics are quite. . . er, interesting. Believe me, most users do not want to go to Joe's DOS shack and cobble up a system of their own. Heck, Atari in 1993 had better call-in technical support than most big clone companies have today!

Fact of the matter is, if you are going to measure performance on MHz, the Falcon falls far behind the times, and becomes obsolete. However, if you choose to measure performance based upon some substantive measure (like how easily you get work done), Falcon keeps up nicely, and a 120

MHz 603e even more so. Keep in mind that PowerPC processors are considerably faster than Pentiums at a similar given clock speed.

I see. I suppose that SoftWindows 3.0 doesn't run Windows 95? Hmmm. . . could have fooled me. As for running applications "at speed," I recall no such promise - only a committment to allow compatibility and enable users to switch from legacy Windows to a more advanced processor with a more-advanced OS.

I chose not to wallow in the past and curse the general computing world. You see, JEDI and others, the computer market is having its last great battle for supremacy. If MS wins, and defeats the open Java coalition, we might as well pack our bags, shelve our Amigas, Ataris, Macs, and Bes, and buy W97 Pentium Pro systems. I don't want to let that happen.

Atari lost the war, not through its users incompetence, but through its own short-sightedness, blindness, and stupidity. Remember the problems Dave Small had getting permission to get TOS for an accellerator board for the Mega ST? Remember Atari's absolute hate of cloning and extensions to the OS? Remember the ST Plus, which was supposed to be a 68020 system with thousands of colors for half the price of a Mac or PC in 1988? Remember the failed launch of the Falcon? I love TOS, I love my Falcon, I like my Mac alot. But frankly, I wanted to participate in the battle against Microsoft, not be a bitter armchair quarterback like yourself.

You see, if MS makes Java WIN32-dependent, you can even forget armchair quarterbacking - you won't have an alternative platform to bash from.

It's common knowledge that retailing is a dying field. Look at Sears, the Macy's bankruptcy, the deaths of major regional stores like Jordon-M, the losses that ComputerCity has heaped on Tandy Corp. Consumers are buying more and more products through the mail, via discount places like TJ Maxx, and the Internet. This is because little value is perceived in the sales experience at a retail store. Every small software retailer from Babbage's to Egghead is losing money and in serious financial trouble. Check the business section of your local paper, or the Wall ST. Journal once in a while. The stories are frequent.

Customers are buying elsewhere - like from Dell and Gateway, both of which have built billion-dollar empires through mail order PCs.

You make that contention - but do not name retail stores. It's not been my experience. So either your mendaciousness has emerged yet again, or experience in your quadrant is severely affected by a reality-distortion field.

As for Apple retail presence "East of the Mississippi", in Boston and greater New England, we have a chain of stores called "ComputerTown" that sells nothing but Mac and Mac-related stuff. It recently expanded and opened its first Non-New England store in Arizona. Macs are for sales in Sears, Circuit City, and numerous other such retail establishments, as well as electronics discount stores and office stores like OfficeMax and Staples.

Of course, you consider success in marketing to be availablity through the dying retail chain, which is seeing NPV revenue flow DECREASE every year since 1990. Why? Because consumers are buying elsewhere, and only a few retailers, specialty ones like ComputerTown, for example, are doing well.

NAKI Rechargeable Battery (with AC Adapter)	$39.00

Call (800) 448-8623 to order, or send e-mail to orders@toad.net!

NEW JAGUAR TITLES NOW AVAILABLE!

Now available for the Atari Jaguar are TOWERS II and BREAKOUT 2000!

Vince Valenti's ST hit TOWERS II is now available for the Jaguar for just $59.95! Available now!!

The all-time arcade classic makes its way onto the Atari Jaguar! Just $59.95!

Also, buy an Atari Jaguar system with Wolfenstein 3D for just $59.95!!! It's a FANTASTIC DEAL! Order TOADAY! FULL SELECTION OF OTHER JAGUAR TITLES

AVAILABLE TOO, WITH SPECIAL PRICES GOOD THROUGH 12/23!!

AMAZINGLY HOT ST STUFF -- PRICES GOOD THROUGH 12/23/96!

This holiday, give the gift of TRUE MULTITASKING with MagiC 5, just $99.00! Or, give what everyone's after, TRUETYPE FONT MANAGEMENT and VDI ACCELERATION with NVDI 4!

MAGIC PC SPECIAL! THROUGH 12/23!!
Get MagiC PC for Windows 95 and run ST programs on your PC -- FAST!
It's just $169.95 -- NORMALLY $189.95 -- through 12/23!! Order TOADAY!

MAGICMAC SPECIAL! THROUGH 12/23!!
Why pay more for MagiCMac, the premier ST emulation software for the Mac!
Through 12/23 pay just $169.95 -- NORMALLY $219.00!! SAVE $50.00!! Works on Power PC and 680x0 machines! Also, get POWER PRINT for Macintosh (use any parallel printer on the Mac or with MagicMac) for just $189.00!!

IMAGECOPY 4.0CD!! JUST $49.95!!
The premier image conversion & printing program for the ST/Falcon is still
available! Also available is the ImageCopy 4.0CD upgrade for just $15.00!!

PAGESTREAM!! JUST $39.95!
PageStream, the best, valuepacked page layout & design program for the ST
is just $39.95!! ORDER YOURS TOADAY!

C-LAB FALCON SPECIAL!! THROUGH 12/23!! PRICES SO LOW, WE CAN'T PRINT THEM!
We've got C-LAB Falcon MK-X, MK-I, and MK-II machines, in 4 and 16MB configurations! If you're interested in getting a quote, please call Jennifer at (410) 544-6943! Available with and without Cubase Audio!!

C-LAB FALCON MK-X UPGRADE KITS! JUST $299!! SAVE $100!
Upgrade your Atari or C-LAB Falcon to the Falcon MK-X expandable, sleek black case for just $299! Available through 12/23 for $100 off the regular
$399 price!

ATARI HARD DISK SPECIAL!! FANTASTIC CHRISTMAS OFFER!
OUT OF THE TOAD VAULTS AND INTO YOUR HOME come these fantastic deals on these VERY CUTE, very SMALL hard disk drives for your Atari ST/TT/Falcon.
They are small, portable SCSI drives available for a LIMITED TIME ONLY!
BUY NOW AND SAVE! Based on 2.5" SCSI drive mechanisms, they are fast and very reliable!

40mb	$ 79.00
80mb	$ 99.00
120mb	$109.00
160mb	$129.00
530mb	$249.00
ICD Link II	$ 99.00

ATARI SM147 MONITORS -- WHERE ELSE CAN YOU GET THEM?
We still have Atari SM147 14" monochrome monitors available for $199 --- all available in time for Christmas delivery. Nothing else comes close!! Great for musicians! 14" display size makes a great upgrade from the SM124! But if you want the SM124, we still have refurbished models for $99 each!

ATARI TTM195 MONITORS -- WE HAVE THEM!
If you need 19" black-and-white clarity on your Atari TT030, there's no substitute for the ATARI TTM195. We have them NEW for $250(!) and a used model for $150(!!) Get yours while they last!! Only a small quantity remaining!

ATARI STACY COMPUTERS!!
If you're looking for the portable power of the Atari STACY, we have refurbished models available for $999! Don't miss this -- this could be your last chance to get one of these classic machines!

ATARI 1040ST and 1040STE Computers!!
We have used Atari 1040ST computers available for $199 and used Atari 1040STE computers available for $299! New STE computers available too! Call for pricing! Order yours today!

HIGH DENSITY DISK DRIVE KITS!
Buy the best ST High Density disk drive kit now for just $89, including the floppy drive! FANTASTIC DEAL!

FALCON POWERUP 2! GO TO 32MHZ with your FALCON030!
Take your Falcon to new speeds for just $79!! Normally $99! SAVE NOW!!

XTRA-RAM DELUXE FOR ATARI ST!
Atari ST 2/4MB RAM UPGRADE AVAILABLE FOR JUST $49.95! NOW THROUGH 12/23/96! GET IT WITH 4 1MB SIMMS FOR JUST $99.95!! SAVE TODAY! OR GET 4 1MB ST SIMMS FOR JUST $49.95! SAVE NOW!

ATARI ST, PC & MAC BEETLE MICE! Beetle Mouse for Atari ST available now through 12/23 for just $29!! SAVE NOW, ORDER TODAY! PC Beetle Mouse PS/2 or Serial just $20, Mac Beetle Mouse just $20!!

Hi Again Steve,

Jedi made a comment that seems to indicate professional software does not exist for the Atari any longer. This is simply not true as I can name a dozen new high end publishing and office tools released in the last year.

The withdrawal of Atari from the market has not affected sales in any way, we still survive on sales of Atari product 100%, with the exception of MagiCMac if you consider that to be a mac application.

All the best,

Chris @ Computer Direct

What components are you refering too? And you get more performance from a 604 at 120MHz than a pentium with the same clock speed.

> I'll believe it when I can buy it. Empty promises and vapourware
> mean nothing to me. We were supposed to be able to run x86 software

>   whenever it is they are supposed to get here...

What number of you using for the cost of X704 computers and were did you
get those numbers? Similarily, where did you get the X704 SPECmarks and
why do you consider them disappointing?

Hi Steve,

What you saw is not an illusion, it is a true representation of the
speed that you can expect in MagiCMac.

MagiCMac is written in highly efficient machine code and takes advantage
of the processing power in that Mac. The MacOS on the other hand is very
slow and sluggish in direct comparison.

The other thing to remember is that all Atari Apps are also written in
highly optimized code and execute and run much faster than Mac apps.
They
are also designed to run on our lowest common denominator machine, a
68000 8MHz 16 bit computer with 1 MB of RAM. Given this hardware
limitation one can quickly see why the software runs so fast when
used on a powerful processor.

If you want more info on MagiCMac, see our web site.

There are many excellent, low cost apps also available and info is
also available on our web site.

All the best,

Chris @ Computer Direct

http://compdirect.com

ps> I forgot to mention that MagiCMac is a true 32 bit pre-emptive
multitasking OS with adaptive prioritization and memory protection.

Six time as fast? Who is this really :). On my much more dated machine,
MagiC Mac indeed runs much faster than the Mac O/S. As you have no
experience with Atari computers, a compairson is not important. What
is, is the fact that you have found a more efficent operating system
for your (all) Mac's and feel the need for speed.
With what you said about "keeping in mind", if you spend the time
finding "Atari" applications that fit your needs, you will end up with

much higher computing performances in all areas. There are many "Atari" applications that perform the same function as those available on the "Mac" platform. Down the the last one, you will benifit from the "speed" increase over the Mac O/S side of your computer.
It is even hard for users of "Real Atari" machines to believe it when they see it.

Mike

Oh, I see, so the BYTE study is wrong. And that Performa 6400/200 is really MORE expensive than the Aptiva. I guess some malicious bastard at Computer City switched the price labels again, eh? :')

I suppose I would be the youngest diagnosed case of Alzheimers in the history of the US if I was, but realistically, I remember no committment to "full-speed emulation." The committment was to speedy emulation (ie, a PowerPC emulates a Pentium a helluva lot faster than a Pentium emulates a PPC), and to Windows NT on PPC. One is here, the latter is in development.

Apple's vision of RISC was to provide users with a more powerful system than the competition could offer. Apple succeeded, as BYTE's study of PowerPC chips demonstrates admirably. PowerPC Macs blew the doors off of comparably priced, comparably equipped Pentia in all areas. I hardly call that "welch"ing.

>   computing.

I see, so there are more hardware platforms available than the ST, Amiga, Mac, and Windoze with some semblance of vendor application support. Oh, forgive me, I forgot the cobble-it-yourself Linux system (no applications, few vendors); the Atari 400/800/XL (Computer Dungeon still services them, at least); the Commodore 64 (discounts on Ghostbusters at K-Mart!); the Timex Sinclair (great little machine), the Coleco Adam (dot matrix printer included!), etc.

No, I'm talking about machines which reached some semblance of market acceptance. This is required to get tools like Internet software, decently-supported word processors, spreadsheets, financial accounting software, and other such applications the world needs to revolve around. For that, only the four aforementioned systems meet the tab. The former two are fading fast. That leaves the latter two in control - and if open standards are not adopted by the market, the chance of success for Be and other new entrants is decidedly slim.

The market has never been at a more crucial crossroads.

The fact of the matter is, unless some development direction is taken, the TOS OS will not be a contender for mass-market approval. And that is what is needed to continue getting useful applications. If the TOS market was rosy, with great sales, you wouldn't see ASH, HiSoft, Oregon Research, etc. halting development and scrambling for other platforms.

I see, and what OS would that be? TOS? If so, I use it too. Got news for you. Very fast, very efficient, still some development. But support is fading every day. And in some key areas that I needed tools in, I couldn't get them. That's why a Macintosh sits next to the Falcon030 on my desk. (Interesting how you assume I don't own one simply because you hate to see the reality of the situation.)

It remains common knowledge that retailing is a shrinking portion of the economy, and continues to shrink. In addition, interestingly enough, CompUSA has been doing so "well" that it has begun a MAIL-ORDER program instead of opening additional stores. Why? Because revenues per square foot are below expectations. Not healthy.

Hmmm. . . JCPenny's is doing well, eh? Could have fooled me. And WalMart? Hardly a retailer - more like a discounter. And a rarity in the large store marketplace right now.

Regardless, it has been more than sufficiently proven that measuring success through retail availability is a 'dinosaur from the last century.'

Yes it is, but if you measure "success" through retail availability, Sears is the best darn example of "retail availability" on the planet.

> $>establishments, as well as electronics discount stores and office stores
> $>like OfficeMax and Staples.
>

>   They have also shown a decline in Mac floorspace as well.

In computer floorspace, as well. Since Apple consolidated Performa into three variations, there is need only for three kiosks. But at the _original_ Staples in Framingham, MA. Mac floor space and software space is growing. And the Staples in Natick gained a Mac display for the first time, displacing those horrible word processing machines (does ANYONE buy those anymore?).

>
>What components are you refering too? And you get more performance from
>a 604 at 120MHz than a pentium with the same clock speed.

     That might mean something if you could get a 604/120 machine
     for $1400 but, you can't (at least not from APS). The $1400
     APS machine touted by you is a 160Mhz 603e based machine. It's
     a nice attempt but not entirely competitive. This is even while
     ignoring the 'El-Cheapo' clones that frighten MacVocates so.

     As far as PC components go: Intel Controllers, ATI 3D graphics chips,
                                 Creative Labs multimedia, Western Digital
                                 PIO Mode 4 (faster than SCSI2) drives &
                                 other big brand brand name items.

     APS Tech's only advertised 604 based system was $2600.

It also supports newer better CPU's natively than just 'ye olde 68000.
And the newest MagiCMac version also has some PPC-native routines.

>   Take that level of efficiency, and then apply the power of a more
>   contemporary machine to it, and the effect you've produced should
>   not be at all unexpected.

Yes, but why should it be otherwise anyway ?

>   Available apps will be limited however. Atari is an orphan.

Yes, but it has "foster parents" like C-Lab and Medusa Computer Systems, both
do various Atari-clone computers. And believe me, they wouldn't be doing
them if it wouldn't be worth it in terms of demand.

>   However,
>   unless you have some pressing professional need, this should not be
>   too much of a problem.

Ahem! This "pressing professional need" can most certainly be satisfied with a
program like CALAMUS SL, which I personally think is much better (and faster)
than PageMaker and QUARK XPress - In terms of typography of course.
And CALAMUS SL runs just fine under MagiCMac.

Anyway running MagiCMac can be seen as an alternative to MacOS, without having to
bypass MacOS. MagiCMac can work as an intregrated unit running fast programs
along with MacOS programs. Use a program like CALAMUS dtp under MagiCMac
along-side with PhotoShop under MacOS and share the files. Many people
do that and it proves to be quite a powerfull combination.
It's just too bad that so few Mac-owners actually knows about MagiCMac,
it could be quite a powerfull system enhancement for their machines and
it would make the MagiC/Atari market grow.

Keep Cool and Flying...

You can also "roll your own" 604 box (like most PC advocates like to)
with Motorola-based motherboards and such.  Check the latest Macworld -
they were listing $2000 for a 604/200/32 with a 2 gig hard drive, roll
your own.
```

Incidentally, the APS clones are a fantastic buy. 160 MHz is plenty fast, and puts easy-to-use computing with a consistent interface and more-refined products in the hands of those who have had enough of defective PCs from Packard Bell and Gateway (oh, the stories I have from experience with THOS two!)

Uh-huh. Your point is?

For real throughput (ie getting useful work done), any modern Macintosh is fully price and speed-competitive with a comparably-priced PC clone. And in many areas, the system integration is 100 times better.

Just try having a layman install RAM, add an Ethernet adaptor and internal CD-ROM to a PC clone. See what happens. I have, and it ain't pretty.

It would be a cheap solution to Apple's current OS woes as well (using a MagiC kernel to replace MacOS). It would probably be more compatible than BeOS, and would offer many developers on the Atari side a platform to develop for that is growing.

A side benefit would be the simultaneous deaths of Jedi and Peter Sinclair-Day. Why, can you imagine Peter's reaction when Apple goes to TOS for kernel salvation? Or Jedi's response to the establishment of Macintosh as the TOS platform of the 90s? Level 25 apoplectic seizure, anyone? <grin>

In article <595cqd$je4@lana.zippo.com> JEDI wrote:

>>Available apps will be limited however. Atari is an orphan. However, unless you have some pressing professional need, this should not be too much of a problem.<<

This is no problem. I recently purchased the Amiga A4060T alluded to in my sig. I like exciting computers, whether they're orphaned or not. :>

In article <595k5s$ecc@scanner.worldgate.com> Chris Krowchuk wrote;

>>What you saw is not an illusion, it is a true representation of the

speed that you can expect in MagiCMac.<<

Very cool!

{much worthwhile info snipped}

>>ps> I forgot to mention that MagiCMac is a true 32 bit pre-emptive multitasking OS with adaptive prioritization and memory protection.<<

Memory protection? Damn, this sounds better all the time. BTW, I visited your website. You'll be hearing from me, though it may not be until February before I can make purchases (the Amiga needs a monitor and a CV64/3D card <g>). I'll definitely be purchasing NVIDI with any package I put together.

In article <32B68402.665B@ridgecrest.ca.us> Michael Grove wrote;

>>Six time as fast? Who is this really :).<<

I really am just a Mac guy who ran this demo, and was mightily impressed. Honest.

Please excuse this weird posting -- I figured I'd do it this way instead of providing three separate ones. Also, please excuse the oddball quoting method -- the AOL newsreader leaves something to be desired in this regard. :>

I should mention that after I demoed MagiCMac I went searching for a review of this OS in MacUser and MacWorld.   There were no articles dealing with it, even though it appears to have been out for a little while. I'll send letters to both magazines suggesting they offer a review. It seems an awful shame that a ready OS with so many features and so much speed, not to mention a useful number of apps, should remain unknown. The way I figure it, this could delay my need for a hardware upgrade for at least a year!

Thanks to all for answering my questions. It really has been a big help. :)

Best;
Steve Duff

Well, Atari apps are considered fast when ported to OS/2 (papyrus, a word processor), why should they be slow on a much faster 604 PPC? They are usually optimized to run acceptably fast on an 8 MHz 68000, most run quite great on a 32 MHz 030 (MPEG players require more power, of course).

Of course, a PPC POVray will always be faster on a PPC than a 030 POVray, but for text editors, word processors, etc., the impression you got was correct.

Thorsten

I wouldn't consider Shockwave to be much of an asset - I mean, come on!
On my Mac, I have allocated ELEVEN MEGABYTES of RAM (silicon RAM, not
VRAM) to Netscape with Shockwave extensions. And I _STILL_ suffer from
"out of memory" errors when I try to, say, visit a basic web page and
read news at the same time. It has sent me running screaming to
Cyberdog (which only takes about 1.4 megs of RAM).

Also, on a 28.8 connection, Shockwave is an abortion to wait for
loading!

```

Of course, but it is an option frequently put forward by PC users. . . A copy of MacUser or MacWorld reads much like a clone mag these days because of the huge content of advertisements for clone systems. DayStar, Motorola, APS, Apple, Power Computing, UMAX, and a number of smaller companies are all making Macintosh compatibles or offering "roll your own" systems. And prices are plunging on all models.

```
> >with Motorola-based motherboards and such.  Check the latest Macworld -
> >they were listing $2000 for a 604/200/32 with a 2 gig hard drive, roll
> >your own.
>
>     Spend that much on a PC of that calibre and you don't have to roll your own.
```

A "PC of that calibre" would cost considerably more, simply because of the slow speed and general inefficiency of the Pentium. It would require a Pentium system running at a 20 to 40% faster clock speed to equal it.

The best PC for $2K I could find (quality PC, that is, not Packard Bell) was a Sony AVIO at COmputer City. I was far from impressed. Incidentally, it was a Pentium 166.

604's outperform Pentiums at equivalent clock speeds on all levels. What this basically translates to is that in all cases, a high end Macintosh system will outperform a high-end Intel system, and that in order to move low end boxes, they have to be priced quite low (with faulty components). Take a look at a Packard Bell's repair rate (or a Gateway's for that matter). I have horror stories in corporate settings about both. As usual, the adage is - you get what you pay for. And they really do make it up later. Ever try calling 900-number tech support?

> >

>   Bear in mind that an 'option' on a Mac Clone might merely be a
>   case that can accept another removable media device.

Depends upon what application you are talking about, how much experience you have, and what you seek to do.

A $1,000 Packard Bell is cheaper than a $1,499 Performa 6360. But with the 6360, you get quality construction, toll-free tech support, and a host of USEFUL programs (like ClarisWorks).

With the Packard Bell, you get a system that is virtually guaranteed to have a major failure that renders it inoperative in a year. You also get a system that is less expandable and made obsolete far sooner than a Macintosh.

Your claim about Mac clone "stripping" is actually an apt description of Packard Bell and MOST bargain-basement PC clones. Ever try to replace the sound card, install SCSI, or add a CD-ROM on one of those? Most require HUGE expenditures in additional hardware because of their "bargain basement" rankings. Their quality is unacceptable.

An APS low-end Mac clone includes 16 megs of RAM, 16 bit stereo sound, keyboard, mouse, a 1.2 gig hard drive, a 160 MHz 603e, IDE and SCSI, ability to use a VGA monitor and PS/2 mouse ports. Hardly a "strippo" system.

Another thing you get with Mac? Real multimedia that's easy to use. PC multimedia is many years behind, unrefined, and a hodge-podge of BIOS-conflicting, IRQ-confusing, expensive, poorly-supported hardware and software. And since multimedia is what many people aim for (even if merely for games), people again get what they pay for.

The multimedia capabilities of that $1,499 Performa 6360 or $1,399 APS blow the $1,299 Packard Bell out of the water.

> >

>
> The Ethernet may be problematic. The typical PC has many options
> in this regard. Not all of them have the same level of complexity.
> Configurability is a triple edged sword.

Yes, it is. Unless you have a Mac. Then, you just plug in the card, install the driver, and go. No "Plug and Pray" like what they typical Windows 95 user experiences. You spend less time installing, and more time working.

And if you do have a problem, Apple doesn't charge for tech support. Microsoft and most clone makers do, directly, through a 900 number, or indirectly, through toll calls (assuming you don't get put on hold for a year.)

You get what you pay for.

> RAM is just a matter of plugging it in. This is no different be it

> Atari ST, Mac, or PC. If they would have problems with this task on a PC, they would fare no better with any other machine (mac incl).

Not hardly. A client of mine had purchased Gateway computers (a bank of them) and installed them (all four) in a 10-Base-T network running Windows NT server and Windows NT workstation. The setup was designed to run SBT Accounting software exclusively.

After suffering from numerous memory problems (the machines ran out of memory, only 32 megs on each "dumb terminal workstation" and 64 on the server), we determined we had a defective batch of machines. Gateway had to be screamed at, while we were down for over two weeks. Finally, the PCs were replaced.

I went to install the new SIMMS in the server (to upgrade it to 128 megs), and couldn't get it to work. Why? The BIOS had to be put through some sort of arcane process before it would recognize the new RAM. That network had so many problems that they ended up hiring a seperate hardware consultant, and, I understand, purchased a new server. Not a glowing endorsement of PC technology.

In a Mac setting, the systems could have been installed by an entry clerk, with minimum help from me. Even if they had gone for the most expensive, least-cost-effective Mac systems, they would have saved tens of thousands of dollars in downtime, new hardware, and consultancy fees.

> The only hitch on a PC internal device is the possibility of plugging it in backwards. The rest is a matter of plugging it in and running the configuration software. If the device is already supported by the current revision of the OS, this isn't even necessary.
>
> Plugging in an IDE socket is much like plugging in a SCSI one.
> Jumpering an IDE drive to master is much like terminating a SCSI dev.
> Plugging in the power is much the same.
> Mounting it in the case is much the same.

Yeah, it's real simple. Just make sure that the BIOS is properly booted. Type AN$1 when the BIOS prompt loads. This takes you to the IRQ layout screen. Write down all the IRQ numbers. Tear out hair. Try various mixtures of IRQ numbers until you find the problem. Spend about four hours doing so. Assign new numbers that Windows NT 4 will find acceptable. Tear out hair. Reboot. Get new driver from hardware maker because it won't allow reassignment. Tair out hair. I've been through all this before, thanks. It ain't Plug and play, no matter what Bill Gates dreams it should be.

> Without more specific details, your anecdotes aren't even that.
>
> Some people have a knack for making their lives difficult no matter what they're using. Others merely don't let the machine intimidate them and just follow the instructions.

I follow(ed) the instructions, all right. Too bad they charge for the
English translation. And any tech support. After all, if you were a
clone maker, with razor thin margins after you gut all quality
components out of your machine - would you want to stand behind your
product? I would - as far behind it as possible.

I see.  That's why InfoWorld, BYTE, and even Intel concur that the 604
is more efficient?

Regardless, the performance (and quality) edge is there.

> >really MORE expensive than the Aptiva.  I guess some malicious bastard

I am someone interested in using tools and telling other people about my
experiences.  And I am tired of seeing Atarians manipulated and lied to
by others.  Fact of the matter is, if a TOS user is considering a
migration, a Macintosh will fit expectations and experiences better than
a PC.  Period.

Nice try.  The industry was thrilled over PowerPC for the same reasons
they were thrilled over the ST and Amiga - it was exciting, new
affordable technology that offered a huge leap over the moribund,
boring, pushed-to-the-limit technology being foisted upon them by other
companies at the time.
```

> Aftermarket software emulation solutions are nothing to hype.

Except that there is no PC-Ditto 95.

> Macs support PC hardware.

Hmmm. . . wonder if a Radius NuBus card would work in a PC? And of course, the PowerMac version of Fractal Design Painter would smoke, right? Oh, forgot, FDP requires System 7, and Executor only runs MacOS 6 with 68000 emulation. . . A slow Mac Plus!

On the other hand, I have Win95 running fine (as fine as it can run) under SoftWindows. When I'm required to run legacy Windows applications, I've got it available.

I see. Which would those be, Alphas? Intel sure isn't offering a Pentium that goes that fast. And the Tanzania boards by Motorola and Apple's upcoming machines will run 604s at 500 MHz. You can even purchase 604 accellerators today that do 300 MHz.

Oh, and also, from experience, Alpha AXP workstations have LOADS of NT applications written for them. I'll bet I've run all three of them in the store!

> in question cost several times more.

Seems you could use a similar argument for the Atari 800 - the only time PC's outperformed an Atari 800 was when they got to 386 levels with 16 bit SoundBlaster cards. Thus, a PC clone is a poor investment, and the Atari 800 is a better buy.

You also ignore the fact that mainstream people want to get work done. A Pentium PC is like a Camaro Z28 with a stripped tranny. Sometimes it works quickly, but it's in the shop a lot, and costs a lot to maintain. And it's been proven, time and again, that professional (and personal) environments running Windows (95 or NT) suffer from greater downtime and are generall less productive than Macintosh environments. You buy a computer to get work done, not just to impress the neighbors.

And too bad that, finally, Macintosh is undeniably faster at the high end than any Intel box, and a better value at the low end.

A PC is a step down from an ST, not a viable migration option.

You do that. While you're doing it, please call Diamond Multimedia and get me their latest Linux drivers, and Creative Media as well. After that's complete, give me a call back. I expect you won't be calling.

>   BTW-Linux runs SCO binaries. If you had the slightest idea
>   what was going on, you would realize the significance of that.

Ah, the Santa Cruz Operation - a blast from the past. They're giving away Xenix for free, now that Linux is out there. Too bad that neither has substantial market acceptance, major applications, technical support, or any sorts of creative tools. It's hardly an option for any but the most computer-nerd oriented. No typical small business or

individual would benefit from a Unix system. The only people who would
are the consultants who charge to keep the system current.

Absolutely. Where can I get a fully graphical compliant HTML program,
with support for Quicktime multimedia and all the other jazz my clients
are looking for, under Linnux? How much will it cost? Can I get tech
support? Is it updated?

I don't recall mentioning UNIX in the above post, either! Seems like
literacy criticisms are misdirected! UNIX is not a mainstream,
mass-market system. It is an OS for hobbyists, academics, and IS-types
in large corporations. It is expensive and poorly-supported, as well as
available in a range of non-compatible configurations. Hardly a decent
choice for small business or the individual.

> >decently-supported word processors, spreadsheets, financial accounting
>
> Linux is supported by Unix vendors, big surprise.

Wow! You can run TeX on it! And you can pay $7,000 for a copy of
FLORCON! Real alternative to the Mac, there!

>

> it has potential.

Actually, I would agree with you there. But what it needs to succeed is
an integrated, fully graphical, consistent interface, provisions for
multimedia, and support (RABID SUPPORT) by a computer maker to succeed.
Without these, it is another NeXTStep.

> It will continue to exist and grow
> regardless of the marketplace.

But so will TOS systems and Macs. And both are more mainstream, have
more software, and more support.

> It is quite independent
>   of it. There are no Tramiels that can destroy it.

Always a good thing - but I don't think Tramiels succeeded. Otherwise, I wouldn't run MagiCMac.

> IT
>   may take quite some time for Linux to be palatable to
>   the masses.

Actually, not really. The next big computer format will be that which appeals to small business and entrepreneurs. One that offers bang for the buck. And one that runs on RISC (which precludes all current generations of Intel processors).

 However, Linux has all the time it needs.
>   It is not tied to one particular set of hardware or the
>   fortunes of one particular corporate entity.

True, but it needs the support of sizable corporate entities to establish the reseller presence to succeed. It would be interesting to see how the Internet comes to bear in this. It also needs to be easy to use, which it is decidedly not, unless you like grepping. "What the hell is 'grepping'?" is the response from the typical computer user.

Hmmm. . . that's interesting. From 1985 to 1989, I remember a market craze which placed Atari at the forefront of technology. I remember a day when Microprose, Sierra-On-Line, WordPerfect, and others supported the ST with regular releases. I even hear that the ST kinda sold okay in Europe (you know, that #1 selling system designation).

Whoopee. Not mass market, not a realistic solution. It lacks the API,
interface, and applications (dare I be P S-D and say apps?) that the
market requires. Thus, it is not a realistic option.

> >for you. Very fast, very efficient, still some development. But

Nope, a person who appreciates elegant, usable, cost-effective tools.
And someone who has to recommend solutions to others (I have completely
gotten out of the PC business because I could not ethically justify
recommending WNT4). What I do know is that in the creative areas (like
my fairly successful Web business), Macintosh computers dominate and
have an unmatched tool-set.

Linux and Windoze don't. TOS doesn't.

Service Merchandise? Another company with failing financials. Lee Wards is not a national chain, at least not one with stores in New England.

>   Furthermore, 'below expectations' != 'unprofitable'.

Yes. In Finance, there is the concept of the "discount rate" - ie, $1 today is 38 cents ten years from now. When cash flows do not meet expectations, net present value of stock declines, shareholder value declines, and weighted average cost of capital increases, constricting ability to make further expenditures. That restriction leads to greater decreases in revenue, further constriction, and, well, you get the idea. See "Commodore International, Ltd. - 1992 to 1994" for more detailed results.

>   That they failed to accurately predict how much space they

>   CompUSA... '-)

No, CompUSA still advertises. :')

>
>   Other retailers are expanding at this time. (Sun,Microcenter)

By and large, though, the retail establishment is dying.

> >
> >Hmmm. . . JCPenny's is doing well, eh? Could have fooled me. And
>
>   Their last quarter profits were up ~30%.

Net income was up, but stock prices weren't. You know why? Cash flow from operations was below expectations. Something that amuses and amazes me is the fixation of net income figures. Cash flow is the measure that the market uses to determine present value.

>
> >WalMart? Hardly a retailer - more like a discounter. And a rarity in

>
>   Typical Macvocate attitude. If it is in-expensive, it is somehow
>   beneath us. 'Discounters' have been around as long as 'retailers'.
>   Walmart != Odd Lots.

I see. Would being a "Macvocate" be similar to being, say, a Jew? Well, hey, the reason I asked is because both labels have been used against me in a negative fashion, assigning me beliefs that I "supposedly have", which assigns me a certain IQ level, and validity. I hardly consider either context to be intellectually becoming or socially acceptable.

Now that we have that out of the way, let us discuss the difference between "retailer" and "discounter." A "retailer" sells specialty goods at substantial markup, with a clearly-outlined marketing strategy. A "discounter" sells a variety of products, whichever it thinks it can sell profitably, with minimal markup, and pursues a price-oriented marketing strategy. Hence the reason that Walmart/K'Mart/Ames/TJ Maxx advertise "we have really, really low prices on everything you want," while Neiman Marcus advertises using those artsy jazz commercials.

>   themselves?

It's not all moving to mail order. . .

Actually, the PC market has moved, to a large extent, to mail order. What makes mail-order PCs sell? I think you can figure that out. Just call Gateway or Dell and ask.

>   Computer Shopper doesn't even seem to have any Mac Clone ads.

Computer Shopper is a PC-oriented rag, and hasn't covered Macintosh with any detail since it dropped Apple II, ST, Amiga, and Mac coverage in 1991.

>   What is visible to most customers in most of the US is a lone
>   brand of Mac drowining in a sea of PC clones.

Then they buy them, and discover the "joys" of daily use. Then the PC goes in the closet, or collects dust, or little Billy uses it to play Doom on and subsequently flunks out of middle school. Sounds rather prejudicial, no? Same with your statement above.

Mac vendors are
>   not doing enough to convince anyone to go against the
>   lemming tide.

I agree, but most are still young companies. They are growing, their marketing budgets are burgeoning, and Motorola is even convincing its Windows NT customers to switch to MacOS. The reall battle is at the creative and small business levels, and on both these fronts, Apple itself is putting on a formidable battle.

I also remember all the hype about IBM "dying" in 1991. Seems to me that the IBM brand, along with Chrysler, International Truck, and American Airlines have all faded into the night because of consumer perceptions generated by ill-informed media spinning. Right?

The Mac version is REALLY buggy, and I suspect that SoftLogik is running low on financial resources. It never had THAT many to begin with, and abandoning the platform that provided it with 30% of its business (TOS), it couldn't have helped itself too much. . .

Also, the situation in the Amiga camp is a tragedy of errors. Seems ESCOM, the company who bought Commodore a full YEAR after Commodore went broke (ie, no development or availability of Amigas for a year), has filed for bankruptcy. No real R&D had been in place at ESCOM to speak of, either. Amiga 1200s and 4000Ts have been sold at the same prices they were in 1992. There's no Amiga PowerPC OS, and availability of machines is dwindling. No R&D is being conducted, and another bidding war has broken out for the Amiga operation. VISCorp (a set-top box company) wants the tech for set-top boxes, and claims to have interest in developing computers (yeah right). Apparently, it's financial backing for a bid has fallen through, and now another gaggle of obscure companies is bidding for Amiga.

Maybe in ten years, we'll see a PowerAmiga, considering the on-again, off-again R&D status. . .

Well, regardless, I'm sure this has hurt SoftLogik as well - lots of Amiga owners have jumped ship.

I admit it, I broke the NDA myself. As long as I've broken it, I might as well mention the rest of the info I know. Apparently, Jack Tramiel got a job at Apple, and appointed Sam T. as director of public relations for new OS development. Hence all the success with Copland and OS public relations as of late. I understand Sam may move up to director of Press Relations for all of Apple, to reassure investors that Apple stock really is a bad deal, and to sell it off, so the T. family can buy it. And Irving Gould is now heading up PowerBook development, and was the man responsible for the fast time-to-market of the PowerBook 5300's revolutionary lithium-ion battery system. :') It even doubles as a portable hand grenade - the Urban Macintosh! (R)

All the above is a joke, don't want to start any rumors. :')

Ahhh, www.intel.com - a great source for non-biased information. And using the IBM AIX terminals to measure clock speeds - pure genius! You're great at bending the rules to fit your wishes!

Let's see the numbers for DayStar, and Apple high-performance computers and compare again. And compare processors to processors, not IBM computers to Intel processors.

BR Miller

Please explain to me why it is impossible to implement sockets in the MacOS.
It is interesting that you consider application implementations of network
services inferior to operating system implementations. IRIX and SunOS
implement sockets as a server (which is just a special kind of application)
while the MacOS does implement networking at the operating system level.

>And by the way CAB is getting better and better by the week. In fact the only

>FreeBSD etc. ?

What is it that you like so much about BSD-sockets? There are other ways
of handling multiple clients by listening on a single port. TLI springs
to mind. Do you like something else about them?

Pagestream is very nice. I was managing 2540 dpi Linotronic output with very nice Adobe Postscript display and text fonts mixed with imported and PGS graphics several years ago. I did several major projects. Everything worked flawlessly! I still use it for hospital forms.

I wonder what happened to the fall '96 release of PGS for the PC line? I think (not sure on this one) that PGS was released for the Mac and, of course, there is still a strong following among the Amiga users.

I know this is advocacy, but I am not really "flame" hunting. Just thought it would be nice to "mention something nice" for a change.

      Around here at places such as OfficeMax, there is a slight bit
      of space for mac hardware and a conspicuous lack of Mac peripherals.
      OfficeMax here doesn't even bother to carry the SCSI Zip100 and
      it could even be said to be a cross platform product (and not just mac).

      Not to mention the cloners. OfficeMax here even has Cyrix-centric
      clones from who knows where (very generic). Everywhere customers
      can look around here Mac dominates. In some respects a Mac user
      would be not unlike an Atari user (in these parts).

      Toad vs. MacMall.

Well, of course it does. You haven't loaded it down with other crap
yet. Excepting excessively bad implementation, any minimized solution
should take less space than a rather maximized and bloated one.

Oddly enough, however, such a beast has no problem on the 'other'
machine. Netscrape+Shockwave+5 or more other open applications at
once manage to function adequately in only 8 Megs of physical ram.

Although, if you're still creeping about on an analog modem, there's
no sense in even looking at shockwave yet. Nevermind that I've yet to

>Oh, I see, so the BYTE study is wrong.  And that Performa 6400/200 is

       No one who understands computer architecture takes them seriously.
       They're about as useful as an SI rating. SPEC, on the other hand,
       uses code more resembling actual applications. Furthermore, the
       test bed machines for both processors more closely resemble each
       other sans processor. SPEC does quite a better job of isolating
       other factors besides the CPU that might effect system performance.

       What performance advantage a Mac may have over a PC is most probably
       due to memory architecture & not the CPU.

>really MORE expensive than the Aptiva.  I guess some malicious bastard

     If that was all that they were promising, then the industry should
     have let out a collective yawn. For what they were promising was
     trivial and already quite commonplace in some areas.

     Aftermarket software emulation solutions are nothing to hype.

     Even the lowly ST has those. SoftWindows being PC-Ditto95 is
     nothing special at all.

     Actually, although not fully supporting System7, Executor does in
     fact support Mac hardware with a greater degree of efficiency that
```

Macs support PC hardware.

>
>Apple's vision of RISC was to provide users with a more powerful system
>than the competition could offer. Apple succeeded, as BYTE's study of

WRONG. The competition can offer 500Mhz NT workstations.
Apple isn't quite up to that yet. The competition can also
offer SMP solutions that will actually take advantage of
multiple processors as opposed to that joke which is DayStar.

>PowerPC chips demonstrates admirably. PowerPC Macs blew the doors off
>of comparably priced, comparably equipped Pentia in all areas. I hardly
>call that "welch"ing.

The only time macs blow the doors off of PC's is when the Macs
in question cost several times more.

Linux is not a commercial venture. For that very reason
it has potential. It will continue to exist and grow
regardless of the marketplace. It is quite independent
of it. There are no Tramiels that can destroy it. IT
may take quite some time for Linux to be palatable to
the masses. However, Linux has all the time it needs.
It is not tied to one particular set of hardware or the
fortunes of one particular corporate entity.

>foot are below expectations. Not healthy.

A Service Merchandise or Lee Ward's model might actually be a good
one. I wouldn't expect a new user to trust some unseen entity with
a costly system.

Furthermore, 'below expectations' != 'unprofitable'.

That they failed to accurately predict how much space they
should use for their rather specialized store does not negate
the concept in general. Perhaps the Tramiels are now running
CompUSA... '-)

Other retailers are expanding at this time. (Sun,Microcenter)
It may be folly but, it is happening nonetheless.
>
>Hmmm. . . JCPenny's is doing well, eh? Could have fooled me. And

Their last quarter profits were up ~30%.

Typical Macvocate attitude. If it is in-expensive, it is somehow

beneath us. 'Discounters' have been around as long as 'retailers'.
Walmart != Odd Lots.

>
>Regardless, it has been more than sufficiently proven that measuring
>success through retail availability is a 'dinosaur from the last
>century.'

Still, if the market is all moving to mail order, then why
aren't any mac mail order vendors making their presence
known outside of those who would make efforts to find them
themselves?

Computer Shopper doesn't even seem to have any Mac Clone ads.

What is visible to most customers in most of the US is a lone
brand of Mac drowining in a sea of PC clones. Mac vendors are
not doing enough to convince anyone to go against the
lemming tide.

>
>Does CAB support Shockwave?

Does it matter? NO!

Most home users don't have the network bandwidth to useably
utilize most of the much harked upon 'plug-ins'. Shockwave
is no exception.

When cheap home network connections can manage effective thruput
of 100Kbps or more, then lack of Shockwave support might be a valid
gripe.

Atarians, try this shockwave out if you can, I suspect that very
few of you will be impressed.

I wonder how much of this shockwave stuff could be implemented with
Instant Graphics or an enhanced version thereof? Tcl/Tk might even
be an improvement...

>
>Uh-huh. Your point is?

You were ranting on about how 604's outperform pentia.

Comparing the performance of a $2600 machine to a $1000 one
is hardly fair. Unless the more expensive vendor is ripping
you off, you should expect more.

>
>For real throughput (ie getting useful work done), any modern Macintosh
>is fully price and speed-competitive with a comparably-priced PC clone.
>And in many areas, the system integration is 100 times better.

'Macintoshes' are NOT price competitive. Some clones are beginning
to be. However, to achieve this, they typically have to strip the
machine to the bones in the process. Add the merest minor options
and even the clones loose any edge.

Bear in mind that an 'option' on a Mac Clone might merely be a
case that can accept another removable media device.

>
>Just try having a layman install RAM, add an Ethernet adaptor and
>internal CD-ROM to a PC clone. See what happens. I have, and it ain't
>pretty.

The Ethernet may be problematic. The typical PC has many options
in this regard. Not all of them have the same level of complexity.
Configurability is a triple edged sword.

RAM is just a matter of plugging it in. This is no different be it
Atari ST, Mac, or PC. If they would have problems with this task

on a PC, they would fare no better with any other machine (mac incl).

The only hitch on a PC internal device is the possibility of plugging it in backwards. The rest is a matter of plugging it in and running the configuration software. If the device is already supported by the current revision of the OS, this isn't even necessary.

Plugging in an IDE socket is much like plugging in a SCSI one.
Jumpering an IDE drive to master is much like terminating a SCSI dev.
Plugging in the power is much the same.
Mounting it in the case is much the same.

Without more specific details, your anecdotes aren't even that.

Some people have a knack for making their lives difficult no matter what they're using. Others merely don't let the machine intimidate them and just follow the instructions.

I concede that preemptive multitasking is very important and that the MacOS should have had it for years. It was just wondering what everyone thinks is so wonderful about sockets. I actually prefer because it offers very graceful disconnects.

That is an interesting claim. According to both BYTEmarks and SPECmarks, the 603e is faster than an equivalently clocked Pentium. The 604e chip similarly outperforms the PentiumPro chips.

Toad's prices for used ST equipment are way too high, IMO. Last week, an Atari dealer offered me a NEW FALCON for $300 (albeit 1MB, no HD). Compare this with the $299 "special" Toad is offering on USED STe's. Also, a few days ago on this very group someone was selling a VERY nice TT for $300. I think people in this group ought to write to Toad and tell them that we are not willing to pay these prices! I know that Toad has long supported the Atari platform, but that is not an excuse to excercise price gouging. If you agree, write to Toad "Toaday" and let them know their prices are way off. I think the Atari community will be better off with realistic prices set for equipment.

The one I like is when one of my fellow citizens complains people don't speak "American".

Or they think New Mexio (state) is part of Mexico (another country).

So you need a Mac to get the job done..Can't the Hades/Direct handle it?

With RD II, can set the memory to 128k-192k...

>Opps, isn't Ram Doubler an application that fixes the fragmented memory
>problems of Macs and utilizes wierd memory locations?

No. It's a replacement for the MacOS virtual memory system (and that's really all it is). Unlike the built-in VM, it does not need to create a swapfile which is the total size of the virtual address space; it grows its swapfile as needed. In order to avoid too much disk activity, it sets aside a RAM buffer where evicted pages are stored in a compressed form. This makes it significantly faster than Apple's VM as long as you don't really overload it (which forces it to go to disk). In general it is faster than Apple VM.

>Is there a FAQ to tell me which version of Ram Doubler to use with
>the version of the Mac O/S I decide to install?

Easy: install the latest version of RAM Doubler. Period. I don't think any of the versions are specific to a MacOS version; they just generally require some form of System 7 (it may be that 7.1 or later is required, I don't remember).

>Can I run three or four versions of Ram Doubler at one time to
>be compatible with software that only supports certian versions of
>Ram Doubler?

No, of course not. Fortunately, that isn't really necessary either.

>If I rename Ram Doubler to Doubler Doubler will I get twice the Ram?

No. But if you hack into it and change the multiplier variable to 6 you will get a virtual address space six times the size of your physical RAM. And if you get RAM Doubler 2.0, you can change between 1x, 1.5x, 2x, 2.5x, and 3x with its control panel. The choice to call the thing RAM Doubler and limit it to multiples of physical memory is pretty much a marketing decision; your VM space can be as large as 2GB (which is the MacOS limit if I recall correctly).

Heh. It's basically a direct connection to the 68040 (or 601 in the case of the 6100) memory bus. The adapter card, in both cases, contains a NuBus controller and a NuBus connector. Not putting the controller on the low-cost machines was a cost savings; I guess Apple figured that the target market traditionally didn't care about expansion cards.

$125 probably wasn't a bad price for the things either. NuBus controllers are expensive for some reason, which is part of the reason Apple switched to PCI. (The other part is of course that PCI kicks butt on NuBus in the speed category. :)

I am looking for an old basic program from the 1980,s that I found in a
mag.
It is a Lie Detector program that used the old game paddles. If anyone
has, or knows where i can get a copy of this program please let me know.

Thank You
Samsams aol

: Well, yes, Canada is part of Americas, North America to be exact. But we
: are not "American". That's a designation that applies distinctly to
: citizens of the United States of America (probably because it sounds cooler
: than calling them "United Statesians").

Where have you been, anyway? Don't you remember.. the U.S. annexed Canada in '93. I think Congress gave the Canadian government $500 and a Smurfs Save the Day cartridge..

I agree with that, the ST/Falcon series keyboards may be long lasting,
but don't have the "touch". The MEGA/TT keyboards are a way better,
but I still prefer PC keyboard, unfortunately the interfaces are quite
expensive compared to the price of a keyboard :-/

Take Care, Miika

>why are you using CorelDraw?
Price. The bundle of CorelDraw, Artisan, WordPerfect, RayDream
all for 99 quid. My level of usage does not justify spending much more
than that on a drawing program. It's to replace DA's Vektor, which
does not run on the PPC.

They would laugh in YOUR face. All the things that they would likely see would indicate to them that you are sadly dellusional. There is nothing in the public eye to indicate to anyone, except those who already have an irrational devotion to apple, that apple is not in decline.

Learn to read sometime. I was not talking of preaching to the choir.

Your actions quite reflect the nature of Apple's marketing incompetence. You go to great efforts to antagonise the group most likely to resist the great hype and fail at any opportunity to show how your beloved machine would better serve than a 10 year old orphan.

Childish posturing devoid of relevant details is all you are capable of.

You are a pathetic advocate.

Their thruput, which you deny much like a frightened little child clinging to it's pillow after a nightmare, would indicate otherwise. Perhaps what is needed is a version of TOS for PPC that completely tosses the MacOS. Then perhaps, full utilization of it's hardware would be attained...

I have been using Atari products for many years. When I was a teenager, a friend had an Atari 800 and I was very impressed with it. I also got an Atari 800 and learned to program a bit on it, played some games, typed in programs, etc. I lost interest in computers for a few years after that. Once I was in college, I started writing a lot and was using an Apple IIe with AppleWorks as my writing tool. I remembered using an Atari several years earlier and looked into getting one again. I would up getting a 130XE with disk drive and Atari Writer Plus and was pleased with the performance, even though I only had 40 columns in my word processor.

Sometime later I found out Atari was still making computers and I bought a used 520ST. I was amazed with the usefulness of the machine. I loved using NeoChrome to draw pictures (an application I hadn't really tried with a computer before). I also started to delve into a little BASIC programming and was very satisfied with the machine. I upgraded to a 1040STe later to run Calamus. I liked Calamus a lot and used it to produce all kind of things at work from bookmarks to flyers to invitations, etc. I then went to an Atari show and bought a Falcon. In the two years I had this machine I started writing reviews of software, using a lot of PD and enjoyed the graphic applications of the machine.

I also bought a Jaguar when it came out (not that I was a big video game player - actually I never had played video games all that much). I was impressed with the system, though, and hoped it would be a sucess.

I also became very disillusioned with Atari - always having to reboot my computer after a crash, no support from Atari Corp., not being taken seriously as a computer enthusiast by others, etc.

So, after hanging in there with Atari for many years, I got rid of all my

Atari stuff. I felt good about it, making a clean slate.

I bought a Windows compatible machine and later upgraded it and started using Win95. Mostly, I use this system for Netscape and other internet applications. I works nicely and I am pleased with it.

However, a nagging memory of Atari stuff still haunted me and I have started re-accumulating a lot of Atari stuff. This time around it feels different because I KNOW the platform is dead and I feel I can really enjoy it. I got an 800XL and am having more fun with it than I could ever imagine having with an 8-bit system - learning more about programming too! I got a Jaguar again because they are really cheap to buy now and I use it to play a game on occasion without worrying whether it's really "64-bit". I have GEMulator on my PC which I can tolerate but don't really like. I'm hoping to get a used Falcon system sometime in the next year.

Has anyone else had this sort of fascination-rejection-and renewal of interest with Atari products? Why do we continue to use/enjoy Atari products? Speaking for myself and just for this week I enjoy Atari because of Iron Soldier on the Jaguar and Music Composer on the Atari 8-bit. Microsoft asks "Where do you want to go today?" Maybe I should say, "Where you yesterday and would you like to go back today."

Let me get this straight...you've got 64 megs of ram and you still get
out of memory errors? Is that right? Geez...Thats not good!

>So you need a Mac to get the job done..Can't the Hades/Direct handle it?

Betcha the Hades/DirecT won't give you out of memory errors with half
that amount of ram, let alone 64 megs!!!

Unfortunately your correct. Most Americans know very little about their own country, let alone another country. What do you expect? The current president can't remember the difference between the Constitution or the Declaration of Indepenence. I feel to be presiden, it should be mandatory knowledge before one can become a candidate.

There's a difference between being quoted with a monitor and being bundled. Was Atari Australia bundling monitors with STs, or were the dealers doing it? I am fairly certain that US Ataris were never sold *by Atari* with a particular monitor bundled.

Macs are not bundled with a monitor by Apple. Dealers don't usually quote prices with monitors, but I suspect that is mostly because there are a lot of possible choices for the customer to make. Monitor buying these days is a matter of figuring out how much money you're willing to pay for size and quality.

When I have tried MagiCMac so far, it doesn't work with virtual memory, period. Apple's VM or RAM Doubler, it makes no difference. I have seen announcements about the upcoming version which say it is now compatible with VM.

> out of memory errors? Is that right? Geez...Thats not good!

It's memory fragmentation. Something any OS suffers from if it is not running VM of some kind. MacOS tends to suffer more because its memory allocation system was designed to let a fairly complex GUI run on a 128K machine; it hasn't aged real well.

>>So you need a Mac to get the job done..Can't the Hades/Direct handle it?
>
> Betcha the Hades/DirecT won't give you out of memory errors with half
> that amount of ram, let alone 64 megs!!!

Sure will. Easy way to do it: run program A that uses 31 MB, run program B that uses 60K, quit program A, run program C that wants 40 MB. On a 64M machine with no VM there will be an out of memory error, because after quitting A there is no free block which is 40 MB. Doesn't matter what OS you are using either.

This is why I run RAM Doubler, even though I have a 64 MB Mac. It gives me a VM system, which eliminates memory fragmentation problems. I could use Apple's VM, but that would require a 65 MB VM file to sit around on my disk all the time, and Apple's is slower than RD anyway.

The NTSC machines didn't need a monitor, they could be connected to a
video
monitor :) (RF or Composite).

As far as Mac's go, get a used 840AV. They run at 40mhz and MagiC
runs quite nicely at that speed on an 040 (more than can be said for
Mac O/S). "Refrbished" ones go for about $1000.00 U.S. MagicC is nice
for Calamus or for that matter most any DTP or WP for TOS, ImageCopy
works great, as does Photoline, GT Look, Kandisky, Lattice C 5.6 and
DEV Pac ect........ Plus you get s-video input with the Mac. With NVDI
you can go up to 800*600 24bit color. Runs like a fast TT with a
graphics
card. According to Gembench, MagiC runs as fast as a Medusa (I think
the reference is to a Medusa 040).

Earlier versions claimed to work with VM (but not RAM Doubler).
The PPC version does NOT run with VM, as it hogs the mmu itself.
I don't know about current 030/040 versions.

Michael Grove <mgrove@ridgecrest.ca.us> writes:
>As far as Mac's go, get a used 840AV.

I can't agree with this recommendation. I would suggest getting a PowerMac.
Depending on which model you get, it can be slower or faster than
the 840 at running MagiCMac programs, but you are likely to migrate
fairly quickly to native Mac programs, in which case the PPC gives a BIG
performance boost. It only took me a year to migrate all my work from
Atari s/w running under MagiCMac to native PPC software running fast
on the PowerMac.

If you never go native, then the 840 is a good bet. But when you realise
what Mac s/w is out there...

Hi Guys,

me again! thanx for telling me the scenes. i thought it was a good
idea to watch this great movie again. so far, i found 4 (!)
appearances of atari in the director�s cut. whow! that�s cool because
it�s a science fiction movie with a plot in the future and as atari is
concerned this future will never happen :(

what about the appearance of atari in terminator 2. where is it ?
(of course i have seen the portfolio, but is there an advertisement
somewhere, too?).

later, dirk

~^~

Yes, the "Smurfs Save The Day" cartridge is on display in the "National
Museum Of Man And Womankind" in Ottawa.

Each year on "Maple Syrup Day", we take it out of the display case and each
person in the country gets a turn playing it. Then we all skate home for some
maple syrup, eh.

CRACKERS
(Remembered as the day the Smurfs came to Canada from hell!!)

For a new machine, you might look at the Performa 6360, or one of the
clone machines in its price range ($1500). At that price level you can
get a 160 to 180 MHz 603e, some form of video input (actually that may
cost extra, I haven't looked at the pricing in detail), and some PCI slots
(probably more of them on a Power Computing machine than a Perf. 6360).
Add Speed Doubler and the machine is guaranteed to exceed the 840AV's
680x0 performance by a factor of 2 (at least), except for FP programs.

I'm not saying this is wrong-but I have a problem with it. I can run
several different Euro-style demos (which as anyone familiar with this
type of coding can attest to) which use almost all of my Falcon's 4 megs
of Ram...I can quit out of one and goto another without having to reboot
or getting "out of memory" errors...I assumed this was good programming,
simply having the exiting program let the system know that the memory
was once again available...

>someone who has used it, anyone?
It's fairly stable. DA's Vektor was the big one to give me problems,
but it's a very buggy program at the best of times.

A few of the things I ran successfully with MMac include Calamus SL,
PageStream, ImageCopy, GemView, ConNect demo (040 only, doesn't
like my PPC), Emacs, Lattice C, Papyrus, DA's Picture, things I'd
written myself...

The VT52 emulator is cack, so text-based programs don't run very well.

As time went on, I found better Mac-native equivalents of the above programs,
and only use MagiCMac for one thing; accessing CIX via the CixComm/CixRead
programs. Now that I've got SoftWindows 95 on the way, even that use
will disappear.

Not necessarily, it depends on the memory model. I could turn off
VM on OS/2 and segmentation was not a problem, as you don't have all
programs sharing a single logical address space.

Can someone explain one aspect of the PowerMac VM to me please?
A Get Info on an application typically says something like "minimum
memory requirement reduced by 1300K if running with VM on".

TOS is no more than a hack put together by the now defunct Digital Research..

TOS has no were the functionality, features and technology that is tied to the
Mac OS.

Give it up Jabba..

Not a weak excuse at all. PowerComputing is backordered.. 50,000 reportedly for the PowerBase alone.. However, Power is shipping in quantity to stamp out that backlog.. Umax/SuperMac is doing well despite that their line has not reached all retailers yet. Motorola started producing their first 20,000 StarMax line. APS will start rolling out this week for their clients..

PowerComputing has done well for a two year company. Power will defantly break a billion in sales in '97'. Wonder why the Tramiels/Atari did not forsee this..

Apple does have marketing issues that need to be addressed. I have mentioned this before.

Considering that there are more than one Mac clone firms, Apple is not the only game in town.. Ain't competition grand? There should be competition to the Hades/Direct to drive those fanatsy prices down..

Still not worth the spending that kind of funds for a non supported platform.
Those funds buy 200Mhz 604e boxes..

> what Mac s/w is out there...

And you will wish you never got started:) After adding a Mac
to my collection, I have been disapointed more times than not
with the quality and pricing of the available software and
hardware. You will really hate the Mac O/S after moving from
the Atari platform (especially if your using a Falcon).
The file system really sucks. Try editing in a directory
containing a couple thousand files, or renaming multiple
file names. Can't be easily done. Kobold handles this without
problem. Go to Walmart and try to purchase some Mac software on
a Friday night binge. Good luck.
There are a few that stand out, but for the most part I favor my
TOS applications. If you really want an inexpensive Atari clone and
want quality apps get a Pentium and stick an Gemulator inside if
all you want to do is run ST software. Quality software at
affordable prices, and inexpensive hardware upgrades are
the norm in the PC world. Windowns NT is nice, I haven't
played with Win 95, and you will find OS/2 will be more to
your liking switching from TOS. If you are currently using
a Falcon, you will miss the DSP software that won't run under
MagiC Mac, but if your looking to see Calamus or Photoline at
800*600 in 24bit go for the Quadra. Video memory for the
Quadra is only about $45.00 to go to two meg and is easily
installed at home. Uses 72 pinn standard simms (60ns) that
can be mixed and matched in whatever configuration.
You also get the ATT DSP which "some" Mac apps utilize
for quicker filtering, and maybe some sound app's make
use of it. For $999.00 its a steal. Don't be ripped off

about this powermac shit. The only reason these guys push
it is they remember how slow the Mac O/S is on an 040
Mac. Running MagiC Mac is a completely different story.
Like the difference in speed over a 1040ST and a TT.
On the Quadra 840AV, Phoenix (Xenomorph) will render
four time faster than my Falcon running from 32mb of Fast
at 32mhz/64mhz FPU. Screen redraws and general desktop
performance is quite impressive as well making the Mac
O/S look like something from running PC Ditto (software
version) on an 8mhz 1040ST.
Anyway I don't think he was asking for advice on which Mac
to purchase for the purpose to "migrate" over to PPC apps,
he ask which Mac would run MagiC Mac the best. By far the most
cost effective method is the Quadra 840AV. With a cheap clock
speeder, you might get up to 46mhz, easily keeping up with the
PPC's running MagiC Mac. You get the Mac onboard video. Which
PPC includes that for under a grand? The cheapest Mac clone
will run you $2200.00 for included video (DC20).

And I was just starting to like you, Brian.

Mike

Wrong! It clearly states in the MagiC Manual, in English,
that VM must be disabled. This has been true for both versions
that Toad has had imported to date.

Does the Hades run MagiC? The only reason for his question, I
think, was that he is looking for an inexpensive way to run TOS
applications. Utilizing MagiC Mac, he can have an 040 TOS
machine for less than anything else on the market. You would
expect to pay more for the performance increase you would see
with the Hades. But at least the option is there, one that allows
several O/S's on a single platform, performance compairable to
the newest machines on the market without having to reinvest
in all new software.
Personally I think that if he is to abandon his Atari machines
he should go with an Intel clone. So much more software and
hardware for soooooo much less money.
But if he is good at Christmas, I would ask for a Hades:)

Of course, you can't handle the truth when it was placed right before you on national news. The left way is always deny everything no matter the truth.

So Stevey, tell us the
> difference(Rush's view) bewtween the two..

First off, you'll have to ask Rush if you want his views. Second, Rush happens to agree with me, not the other way around. I unlike most liberals I know, can think for myself without the govermant doing it for me. It is I and 84% of this nation(consevatives) that put Rush where he is and not the other way. Liberals are always trying to say Rush listeners are mindless. The fact is your just jealous because no one likes or listens to liberals and this is why you have no voice in talk radio, becuase all who have tried have failed, Penis. Why have they failed? They have failed because liberalism is not at all a mainstream idea. You just don't get it do you?

>
> Four more and 8 more for Gore, get over it..

Don't count on it to hard Penis. That is if you can count.

>
> When Ragun was in office, we got on with our lives..

Ragun was never in office. Reagan was however and you liberal scum didn't let up for 12 years and now even with your prez, you still aren't satisfied and still bitch about Reagan. You Commies wont be happy until this country is a total socialist nation. Clinton wont effect me because I know how to survive without the government unlike your self and millions of liberals like you who feel it is the only hope. Such a pity.

> Bloated sig deleted indeed!!

Join the Telegames list. As a result of the list, 4 new games will be released for the JAguar. Show your support!!!! Contact Telegames at http://www.telegames.com

1) Breakout2000 (Dec. '96)
2) TowersII (Dec. '96)
3) Worms (Jan. '97)
4) Zero 5 (Feb. '97)

All can be pre oredered from Bits O' Fun at 1-800-FUN-JAGS. Dave is a great guy and has some deals for you if you order several. Tell him Krunch sent you. :)
Remember, is it the squeaky gear that gets the grease. Make sure you order some of these as they are all excellent games and Telegames has said they will release more based on the successes of this run of games. Help me help you get the games you want! :)
How would you feel about Jaguar shareware and would you be willing to pay money for a hardware add on that allowed it? Developers Welcome.

Vote for the games you want to see @ Kitten Litter

A lot of my crashes happened because of conflicting software, especially
AUTO folder programs conflicting with each other/programs I was running.
I like the way Win95 can "recover" from a crash without having to reboot
the system versus the way the Atari locked up.

As to support from Atari
Corp., one example I want to point out is that when I bought my Falcon, I
bought TruePaint with it. The grid function didn't work properly and
after calling the distributor and trying various things, we discovered
that the problem occured only under TOS 4.02 and not 4.04. Since I had

just bought my Falcon and it was still under warantee, I asked to exchange it for a model with TOS 4.04. Atari said "no can do." My dealer said that "in a couple of months" Atari was going to release 4.04 as a chipset that I could buy for around $60 + installation costs. I'm not sure whether TOS 4.04 ever became available as a separate package you could buy. Contrast this with Packard Bell - I bought a Win 3.1 computer from them and later they sent me a free upgrade to Win95 because I had bought my machine within the last 6 mos.

As to not being taken seriously by other computer enthusiasts - I'm sure this is something that everyone who uses Atari has had to put up with from time to time.

>

Well, yes, that is why I posted in an advocacy group :) But I'm not really knocking Atari by calling it "dead." I know that there are some really dedicated developers who are still working to produce some things for the Atari and I congratulate them on their effort. I call Atari "dead" now because I don't think that there is any chance of mass-market acceptance of the platform. The Atari 8-bit is "dead" too, but there are still some developers for it and many enthusiasts. Calling a platform dead is not really an insult. (Of course, when Business Week put Apple's logo on their cover with the headline "Death of an American Icon" I thought that was insulting - and premature, somewhat like Mark Twain said, "The reports of my death have been highly exagerrated.")

>

> tolerate?,
>

Well, GEMulator works well for an emulator, I guess. But it is not anything like the real thing. I have noticed especially that in drawing programs I do not have the control of the mouse that is needed (may be due to a too slow PC). Also, after working with a Falcon, the speed, lack of high resolution-color support, and lack of Falcon compatibility is VERY noticeable. I also have a lot of file management control problems, like trying to import text into Calamus, copying from floppies, etc. I would much rather have a real Atari than the GEMulator.

As I said, if you cared to read it instead of just rudely shouting
"wrong", older versions worked with VM. If Toad (whoever they are)
have only imported two versions, then they clearly haven't imported
them all.

VM support was changed when the PPC-compatible version was produced.

You know, Degas Elite, NeoChrome, the latest MegaDemo...
Nope, I'd rather let the "pros" handle that, but take, f.ex. APEX Media,
most image processing programs (An image file isn't automagically shrunk,
just because the programs are), recording software, etc.

Sorry, I think that I might have been wrong about QuickTime 2.5 having a
MPEG codec. I got the MPEG codec with the last develop and didn't
realise that it was not release software. BTW, I think that you mean
MoviePlayer not Apple Video Player.

Petey-boy, don't fool around: you already admitted to have _40_ megabytes
of RAM in your Mac. That's approximately thrice the memory of above Fal-
con.

Hurm, I thought the MPEG codec was released. In any case it has been in
beta status long enough that if it is not out already it should be very,
very soon now.

I believe QT 2.5 has had the hooks all along to support MPEG, it's just
that they needed more time to finish up MPEG and didn't want to hold up
the release of 2.5.

> SO compare a 200 mhz 603e to a 120 mhz 604!!! The new 6400 is $2800.00, and can't even do serious image editing! Stock, only 16-Bit color, and VRAM is only 1 meg. (NON-UPGRADEABLE!) This limits you to only 256 hues of a color at one time, unless you want to spend more money on a PCI card! (Oh, the monitor is -not- included in that $2800 price either!)

Erm, try $2050 from MacMall, after $150 rebate.

(That's for the 16M RAM, 2.4G HD, 8x CD, 28.8 modem model. No, the monitor isn't included in that price either.)

A better deal by far is the Power Computing PowerBase 200, at $1795 for 16/1.2/8xCD. It is essentially the same motherboard as the 6400, except that Power Computing substituted an ATI 3D accelerator video chip for Apple's video chip, and it has 2MB EDO RAM for video. It is also available at 180 MHz ($1495) and 240 MHz ($2195). Add $100 to any of them to get the mini-tower case instead of desktop.

There is also a Motorola StarMax 200 MHz 603e, 16M/1.2G/1M vid/8xCD at $2K. SuperMac has the C600 (200 MHz 603e, 16M/2.1G/?vid/8xCD) at $1895. I believe both of these are based off a Motorola motherboard.

With three major clone lines, Apple is defintely no longer the only company to think about when buying a Mac. When CHRP finally gets rolling, things should get really good.

I don't remember the exact scene, but I think
it was a sign on the side of a building
down at the end of a street scene.

Mike

You should be concerned about where to wipe the crap off your fingers
after
you wipe. Even though the shiet you spread is thin, you must still
stink.
Everything you say is false. You quote false prices, performances, and
